Lauren Block
Baruch College, City University of New York

Leonard Lee
National University of Singapore

The 50th Annual Conference of the Association for Consumer Research (ACR) was held at the Hyatt Regency in Atlanta, Georgia from October 17-20, 2019.

This conference marked ACR’s Golden Anniversary—fifty years of an interdisciplinary, cross-method, international association of scholars building knowledge on all aspects of consumers’ thoughts, decisions, and behaviors. Thus, our conference theme was Becoming Wise. This theme of Becoming Wise was integrated across our competition papers, special sessions, Knowledge Forums, WorkShops and LearnShops. What is wisdom? It is an acknowledgment of our past: our accumulated base of scientific learning, our pot of generally accepted beliefs, and the written and oral transmissions of our teachers and mentors. But it is more than that. It is our present, our now. It is our ability to discern what is true and right, and to couple that with what is just. To be wise is to make good judgments and to behave with sagacity. To that end, we are always Becoming Wise.

The conference attracted over 1200 participants from 41 different countries across the globe. We received 1070 total submissions and accepted 654, which represents a 61.12% acceptance rate. This year’s conference presented 280 competitive papers (acceptance rate of 52.14%), 62 Special Sessions (56.36% acceptance), 7 video submissions, 11 Knowledge Forums, and 10 Invited WorkShops and LearnShops.

We thank our generous sponsors: Sheth Foundation, University of British Columbia Sauder School of Business, University of Florida Warrington College of Business, University of South Carolina Darla Moore School of Business, The University of Oregon Lundquist College of Business, California State University, Northridge (CSUN), Journal of the Association for Consumer Research, Journal of Consumer Research, Society for Consumer Psychology, SONA Systems, Stukent, Inc., LINKS Simulations, BIOPAC Systems, Inc., Palgrave Macmillan, the Marketing Science Institute (MSI), and University of Chicago Press.

Many wonderful people worked tirelessly to help us make this conference possible. We thank our Program Committee, Competitive Paper Reviewers, Working Paper Reviewers, and Videography Reviewers. We especially wish to thank Derick Davis, Rhonda Hadi, and Lama Lteif (Working Paper Chairs), Jennifer Escalas, Laura Peracchio, and Tiffany B. White (Sharing Stories Chairs), Joonas Roka and Ekant Veer (Videography Chairs), and Keisha Cutright and Thomas Kramer (Doctoral Symposium Chairs). Many thanks also go to our excellent Associate Editors: Cindy Cai, Amber Epp, David Faro, Markus Giesler, Mathew Isaac, Yuwei Jiang, Tina Lowrey, Pragya Mathur, Brent McFerran, Maureen Morrin, Jeffrey Parker, Vanessa Patrick, Yael Steinhart, Manoj Thomas, Claire Tsai, Beth Vallen, Alice Wang, and Meng Zhu.

Special gratitude goes to ACR Executive Director Rajiv Vaidyanathan, our Conference Planners Paula Rigling and Melissa Morris, our graphics designer Roy Wiemann, and the ACR Executive Assistant Brenda Monahan.

Last but not least, we wish to sincerely thank Darren Dahl, ACR President 2019, for gifting us with the opportunity to organize the ACR conference and for his unconditional support and enthusiasm during the entire journey.

Rajesh Bagchi, Virginia Tech, USA
Lauren Block, Baruch College, City University of New York, USA
Leonard Lee, National University of Singapore, Singapore

2019 Conference Co-Chairs
Conference Committees & Reviewers

PRESIDENT
Darren Dahl, University of British Columbia, Canada

CONFERENCE CHAIRS
Rajesh Bagchi, Virginia Tech, USA
Lauren Block, Baruch College, CUNY, USA
Leonard Lee, National University of Singapore, Singapore

ASSOCIATE EDITORS
Tina Lowrey, HEC Paris, France
Pragya Mathur, Baruch College, CUNY, USA
Brent McFerran, Simon Fraser University, Canada
Mimi Morrin, Temple University, USA
Jeffrey Parker, University of Illinois at Chicago, USA
Vanessa Patrick, University of Houston, USA
Yael Steinhardt, Tel Aviv University, Israel
Manoj Thomas, Cornell University, USA
Claire Tsai, Toronto University, Canada
Beth Vallen, Villanova University, USA
Alice Wang, University of Iowa, USA
Meng Zhu, Johns Hopkins University, USA

WORKING PAPER CHAIRS
Derick Davis, University of Virginia, USA
Lama Lteif, University of New Mexico, USA

DOCTORAL SYMPOSIUM CHAIRS
Keisha Cutright, Duke University, USA
Tom Kramer, University of California at Riverside, USA

VIDEOGRAPHY CHAIRS
Ekant Veer, University of Canterbury, New Zeland

PROGRAM COMMITTEE
Stacey Finkelstein, Stony Brook University, USA
Eileen Fisher, York University, Canada
Nitika Garg, UNSW, Australia
Tanuka Ghoshal, Indian School of Business, India
Joseph Goodman, Ohio State University, USA
Zeynep Gurhan-Canli, Koc University, Turkey
Kelly Haws, Vanderbilt University, USA
William Hedgecock, University of Iowa, USA
Kelly B. Herd, University of Connecticut, USA
Stefan Hock, George Mason University, USA
Joey Hoegg, University of British Columbia, Canada
Ming Hsu, University of California Berkeley, USA
Szu-Chi Huang, Stanford University, USA
Dawn Iacobucci, Vanderbilt University, USA
Caglar Irnak, University of Miami, USA
Uzma Khan, University of Miami, USA
Blair Kidwell, University of North Texas, USA
Minjung Koo, Sungkyunkwan University, Republic of Korea
Aradhna Krishna, University of Michigan, USA
Aparna Labroo, Northwestern University, USA
Ashok Lahiri, Indiana University, USA
Cait Lamberton, University of Pittsburgh, USA

Advances in Consumer Research (Volume 47) / ix
# Table of Contents

Preface ........................................................................................................................................ iii
Conference Committees & Reviewers ......................................................................................... iv

## 2019 ACR Presidential Address

### The Value of Wrong
Darren Dahl, University of British Columbia, Canada ................................................................. 1

## 2019 ACR Fellow Addresses

### Looking Back
William O. Bearden, University of South Carolina, USA ............................................................ 4

## 2019 ACR Fellow Addresses

### Puzzles: Anticipating the Consequences of a Paradigm Shift in Consumer Research
Chris Janiszewski, University of Florida, USA .............................................................................. 6

## 2019 ACR Fellow Addresses

### The Fellowship and The Quest
Linda L. Price, University of Oregon, USA ..................................................................................... 13

## Special Session Summaries

### The Emotional Consumer: Insights from Big Data
Chairs: Matthew D. Rocklage, Northeastern University, USA
Jonah Berger, University of Pennsylvania, USA

#### Paper #1: What Leads to Longer Reads? Psychological Drivers of Reading Online Content
Jonah Berger, University of Pennsylvania, USA
Wendy W. Moe, University of Maryland, USA
David A. Schweidel, Emory University, USA

#### Paper #2: The Enhancing vs. Backfiring Effects of Emotionality in Consumer Reviews
Matthew D. Rocklage, Northeastern University, USA
Russell H. Fazio, Ohio State University, USA

#### Paper #3: Managing Online Venting: The Impact of Temporal Distance on the Perception of Negative Online Reviews
Lauren Grewal, Dartmouth College, USA
Andrew T. Stephen, University of Oxford, USA
Yakov Bart, Northeastern University, USA

#### Paper #4: Engaging Your Audience on Social Media: An Application to Politics
David A. Schweidel, Emory University, USA
Beth L. Fossen, Indiana University, USA
The Power of Product Packaging: Changing Perceptions and Living a Healthier Life

Chairs: Sheng Bi, Washington State University, USA
Maureen Morrin, Temple University, USA

Paper #1: The Unbearable Heaviness of Information: More Product Information = Higher Product Weight
Sheng Bi, Washington State University, USA
Kunter Gunasti, Washington State University, USA

Taku Togawa, Chiba University of Commerce, Japan
Jaewoo Park, Musashi University, Japan
Hiroaki Ishii, Seikei University, Japan
Xiaoyan Deng, the Ohio State University, USA

Paper #3: The Effect of Packaging Typeface on Product Perception and Evaluation
Xiaoyan Deng, The Ohio State University, USA
Alysha Fligner, Husky Energy, USA

Paper #4: Is Matte the New Black? The Impact of Learned Associations on Perceptions of Food Healthfulness
Ning Ye, Temple University, USA
Maureen Morrin, Temple University, USA
Kristina Kampfer, Kanter Added Value, Germany

From Words to Wisdom in Conversational Language and Paralanguage

Chairs: Shirly Bluvstein, New York University, USA
Juliana Schroeder, University of California, Berkeley, USA

Shirly Bluvstein, New York University, USA
Xuan Zhao, University of Chicago, USA
Alix Barasch, New York University, USA
Juliana Schroeder, University of California, Berkeley, USA

Paper #2: How Concrete Language Shapes Customer Satisfaction
Grant Packard, York University, Canada
Jonah Berger, University of Pennsylvania, USA

Paper #3: Nonverbal Mimicry of Textual Paralanguage
Andrea Luangrath, University of Iowa, USA
Joann Peck, University of Wisconsin-Madison, USA
Victor Barger, University of Wisconsin-Whitewater, USA
Abby Haynes, University of Iowa, USA

Paper #4: The Impact of Dialogue Dynamics in Online Service Resolution
Francisco Villarroal Ordenes, University of Massachusetts-Amherst, USA
Dhruv Grewal, Babson College, USA
Lauren Grewal, Dartmouth College, USA
Panagiotis Sarantopoulos, University of Manchester, UK

Touch, Voice, and Kinetics: Interactive Influences on the Tech-linked Consumer

Chairs: Yanliu Huang, Drexel University, USA
William Hampton, University of St. Gallen, Switzerland

Paper #1: Horizontal Touch Interfaces and the Illusion of Discrete Content
S. Adam Brasel, Boston College, USA

Paper #2: Good Buzz, Bad Buzz: Using Vibrotactile Feedback to Shape Consumer Choice
William Hampton, University of St. Gallen, Switzerland
Christian Hildebrand, University of St. Gallen, Switzerland

Paper #3: Augmented Reality Helps Low-Involved Consumers Build Self-Brand Connection
Jae Jaeyeon Chung, Rice University, USA
Youjung Jun, Columbia University, USA

Paper #4: Understanding Consumer’s Product Decisions When Shopping by Voice
Zhen Yang, Creighton University, USA
Yanliu Huang, Drexel University, USA
Barbara Kahn, University of Pennsylvania, USA
Jiangen He, Drexel University, USA
How Do Consumers Value their Private Data? ................................................................. 40
Chairs: Geoffrey Tomaino, INSEAD, Singapore
Klaus Wertenbroch, INSEAD, Singapore
Daniel Walters, INSEAD, France

Paper #1: The Bulletproof Glass Effect: When Privacy Notices Backfire
Aaron R. Brough, Utah State University, USA
David A. Norton, University of Connecticut, USA
Leslie K. John, Harvard Business School, USA

Paper #2: Telling Your Secrets to an AI: Consumers Prefer Disclosing Private Personal Information to an AI (vs. a Human)
Tae Woo Kim, University of Technology Sydney, Australia
Li Jiang, The George Washington University, USA
Hye Jin Lee, Indiana University, USA
Adam Duhachek, Indiana University, USA

Paper #3: Consumers Place a Lower Value on Private Data When Exchanged for Goods as Opposed to Money
Geoffrey Tomaino, INSEAD, Singapore
Klaus Wertenbroch, INSEAD, Singapore
Daniel Walters, INSEAD, France

Paper #4: From Privacy Concern to Privacy Mindsets
Aaron R. Brough, Utah State University, USA
Kelly D. Martin, Colorado State University, USA

The Modern Consumer: How New Technologies are Changing Consumer Behaviors and Interactions ......................................................... 45
Chair: Shiri Melumad, University of Pennsylvania, USA

Paper #1: Technology-Mediated Innovation
Melanie S. Brucks, Columbia University, USA
Jonathan Levav, Stanford University, USA

Shiri Melumad, University of Pennsylvania, USA
Robert Meyer, University of Pennsylvania, USA

Paper #3: Dehumanization in the IoT: Experiential Consequences of Syntactically Constricted Human-Machine Interaction
Christian Hildebrand, University of St. Gallen, Switzerland
Donna Hoffman, George Washington University, USA
Tom Novak, George Washington University, USA

Paper #4: Improving Civil Discourse: Speaking is a More Humanizing Form of Discourse Than Writing
Juliana Schroeder, University of California, Berkeley, USA

The Changing Face of Luxe:
Refocusing, Undermining, Moralizing Luxury ................................................................. 51
Chair: Yajin Wang, University of Maryland, USA

Paper #1: From “Wealth-as-Status” to “Value-as-Status:” The Millennial Luxury Consumer Mindset
Ludovica Cesareo, Lehigh University, USA
Vanessa Patrick, University of Houston, USA

Paper #2: Picasso, Monet, and Louis Vuitton: Appreciation of Arts Dampens Desire For Luxury Goods
Yajin Wang, University of Maryland, USA
Alison Jing Xu, University of Minnesota, USA

Paper #3: Hurts So Good: Status Products That Incur Environmental Costs are Preferred by Status-Striving Consumers
Morgan K Ward, Emory University, USA
Sara Loughran Dommer, Georgia Tech, USA
Darren Dahl, University of British Columbia, Canada

Paper #4: Do Fighters Wear Prada? Consumer Dominance Orientation and Desire for Luxury Brands
Perrine Desmichel, HEC Lausanne, Switzerland
David Dubois, INSEAD, France
Bruno Kocher, HEC Lausanne, Switzerland
Effects of Sensory Ambient Factors on Purchase and Consumption of Food and Non-Food Products ................................................................. 57
Chair: Dipayan Biswas, University of South Florida, USA

Paper #1: Effects of Synthetic and Analytic Graphical Front-of-Pack Labels on the Nutritional Quality of Supermarket Food Purchases: Evidence from a Large-Scale Randomized Control Trial
Pierre Chandon, INSEAD, France
Pierre Dubois, Toulouse School of Economics, France
Paulo Albuquerque, INSEAD, France
Olivier Allais, INRA, France
Céline Bonnet, Toulouse School of Economics, France
Patrice Bertail, University Paris Nanterre, France
Pierre Combris, INRA, France
Saadi Lahlou, London School of Economics and Political Science, UK
Natalie Rigal, University Paris Nanterre, France
Bernard Ruffieux, Grenoble Applied Economics Lab, France

Paper #2: Going My Way? The Effect of Perceived Lighting on Perceptions of Provision and Elimination
Kevin L. Sample, University of Georgia, USA
Julio Sevilla, University of Georgia, USA

Paper #3: Effects of Retail Ambient Color on Purchases of Indulgent Foods: Findings from Field and Lab Studies
Dipayan Biswas, University of South Florida, USA
Courtney Szocs, Louisiana State University, USA
Annika Abell, University of Tennessee (Knoxville), USA

Paper #4: Hot or Cold? How Ambient Temperature Influences Calorie Consumption
Jayati Sinha, Florida International University, USA
Rajesh Bagchi, Virginia Tech, USA

Ads, Advocates, and Allies in Navigating the Road from Marginalization to Legitimation .............................................................. 62
Chairs: Steven Shepherd, Oklahoma State University, USA
Abigail Nappier Cherup, University of Nebraska-Lincoln, USA

Paper #1: The Ally Effect: The Role of Implicit and Explicit Cues in Advertising Towards Marginalized Groups
Abigail Nappier Cherup, University of Nebraska-Lincoln, USA
Meike Eilert, University of Kentucky, USA

Paper #2: Sincere, Not Sinful: The Unique Role of Brand Personality in Shaping Liberals’ and Conservatives’ Views of LGBT Ads
Steven Shepherd, Oklahoma State University, USA
Tanya L. Chartrand, Duke University, USA
Gavan J. Fitzsimons, Duke University, USA

Paper #3: When Consensus Is Lost: Mobilizing Capital to Establish Consumer Legitimacy
Sunaina R. Velagaleti, Ignite360, USA
Amber M. Epp, University of Wisconsin-Madison, USA

Paper #4: Effective Advertising to the LGBTQ Communities: An Exploratory Study
Erica Ciszek, The University of Texas at Austin, USA
Kathrynn Founders, The University of Texas at Austin, USA

Consuming Information Online:
Perspectives on the Context-dependent Effects of News and Reviews .......................................................... 68
Chair: Jared Watson, New York University, USA

Paper #1: The Effects of Engagement Metrics on Media Consumption: A Persuasion Knowledge Account
Sokiente (Tari) Dagogo-Jack, Boston College, USA
Jared Watson, New York University, USA

Paper #2: Ratings and/or Reviews: The Effects of Aggregate and Disaggregate Product Information in Product Evaluations
Jared Watson, New York University, USA
Anastasiya Pochepstova Ghosh, University of Arizona, USA

Paper #3: The Role of the Mode in Product Evaluations and Choice
Daniel Villanova, University of Arkansas, USA
Elise Chandon Ince, University of South Carolina, USA
Rajesh Bagchi, Virginia Tech, USA

Paper #4: Does Gender Matter? The Effect of Management Responses on the Distribution of Online Reviews
Davide Proserpio, University of Southern California, USA
Isamar Troncoso, University of Southern California, USA
Francesca Valsesia, University of Washington, USA
Time, Discounting, and the Consumer Experience

Chairs: Evan Weingarten, University of California, San Diego, USA
Annabelle Roberts, University of Chicago, USA

Paper #1: Duration Sensitivity of Key Moments
Kristin Diehl, University of Southern California, USA
Evan Weingarten, University of California, San Diego, USA
Gal Zauberman, Yale University, USA

Paper #2: The Sign Effect in Past and Future Discounting
Sarah Molouki, University of Chicago, USA
David J. Hardisty, University of British Columbia, Canada
Eugene M. Caruso, University of Southern California, Los Angeles, USA

Paper #3: Love is Patient: People are More Willing to Wait for Things They Like
Annabelle Roberts, University of Chicago, USA
Franklin Shaddy, University of Southern California, Los Angeles, USA
Ayelet Fishbach, University of Chicago, USA

Paper #4: Discounting a Lump-sum vs. a Payment Stream: More Payments Leads to More Patience
Selin A. Malkoc, The Ohio State University, USA
Joseph K. Goodman, The Ohio State University, USA
Moshe Rosenboim, Ben-Gurion University of the Negev, Israel

Perceptions of AI and Algorithmic Decision Making

Chairs: Gizem Yalcin, Erasmus University, the Netherlands
Nofar Duani, New York University, USA

Paper #1: Risk Seeking Preferences Lead Consumers to Reject Algorithms in Uncertain Domains
Berkeley J. Dietvorst, University of Chicago, USA
Soaham Bharti, University of Chicago, USA

Paper #2: The Expert vs. the Algorithm: Consumers’ Perceived Competence Impacts Their Valuation of Product Recommendations
Gizem Yalcin, Erasmus University, the Netherlands
Anne-Kathrin Klesse, Erasmus University, the Netherlands
Darren Dahl, University of British Columbia, Canada

Nofar Duani, New York University, USA
Alixandra Barasch, New York University, USA
Vicki Morwitz, Columbia University, USA

Children as Consumers: Children’s Affective and Cognitive Processes for Financial and Health Decisions

Chairs: Michal Maimaran, Northwestern University, USA
Szu-chi Huang, Stanford University, USA

Paper #1: Show Them the Money: Children’s Affective Responses to Spending and Saving Predict Their Spending Behavior
Margaret Echelbarger, University of Chicago, USA
Susan A. Gelman, University of Michigan, USA
Scott I. Rick, University of Michigan, USA

Paper #2: Use of Sensory Food Imagery to Drive Children to Choose Smaller Portions of Healthy and Unhealthy Snacks
Sophie Nicklaus, INRA, France
Camille Schwartz, INRA, France
Christine Lange, CNRS, France
Yann Cornil, UBC, Canada
Pierre Chandon, INSEAD, France

Paper #3: Using Coupons to Motivate Children to Purchase Healthy Snacks in Boston-Area Convenience Stores
Sean B. Cash, Tufts University, USA
Anna R. McAlister, Endicott College, USA
Christina D Economos, Tufts University, USA
Megan E Lehnerd, Framingham State University, USA
Suzanne Howell, Brigham and Women’s Hospital, USA
Kaela Plank, Nutrition Policy Institute, USA

Paper #4: Children are Price Sensitive Too: Using Price Promotions to Increase Children’s Choice of Healthy Food
Szu-chi Huang, Stanford University, USA
Michal Maimaran, Northwestern University, USA
Pain of Paying: Antecedents and Consequences............................................................... 88
Chairs: Elizabeth M. S. Friedman, Columbia University, USA
Ryan Hauser, Yale University, USA

Elizabeth M. S. Friedman, Columbia University, USA
Ryan Hauser, Yale University, USA
Ravi Dhar, Yale University, USA

Paper #2: The Perception, not the Payment: How Cognitive Appraisal Influences Pain of Paying
Justin Pomerance, University of Colorado Boulder, USA

Paper #3: More of the Same: Higher Pain of Payment Decreases Variety Seeking
Liang Huang, University of Arizona, USA
Rafay Siddiqui, The Hong Kong Polytechnic University, Hong Kong
Anastasiya Pochepsova Ghosh, University of Arizona, USA

Paper #4: How the Pain of Payment Can Magnify and Mitigate Choice Overload Effects
Avni M. Shah, University of Toronto, Canada
James R. Bettman, Duke University, USA
John Payne, Duke University, USA

Prosocial Consumption and Contribution: The Impact of Firm’s Actions, Donor’s Actions, the Nature, and the Machines . . . . 93
Chairs: Szu-chi Huang, Stanford University, USA
Fangyuan Chen, Hong Kong Polytechnic University, China

Paper #1: Risky Business: The Risk-Reward Trade-off is Different for Nonprofit and For-Profit Firms
Rachel Gershon, University of California, San Diego, USA
Cynthia Cryder, Washington University in St. Louis, USA
Merriah Croston, Washington University in St. Louis, USA

Paper #2: Increasing Donor Retention with Feedback on Donation Use
Edlira Shehu, Copenhagen Business School, Denmark
Michel Clement, University of Hamburg, Germany
Karen Page Winterich, Pennsylvania State University, USA
Besarta Veseli, University of Hamburg, Germany

Noah Castelo, Columbia University, USA
Miranda Goode, Western University, Canada
Katherine White, University of British Columbia, Canada

Paper #4: When Robots Come to Our Rescue: Why Professional Service Robots Aren’t Inspiring and Can Demotivate Consumers’ Prosocial Behaviors
Szu-chi Huang, Stanford University, USA
Fangyuan Chen, Hong Kong Polytechnic University, China

Markets and Material Arrangements.................................................................................. 99
Chairs: Hope Jensen Schau, University of Arizona, USA
Melissa Archpru Akaka, University of Denver, USA

Paper #1: Neoliberalism: The Paradox of Responsibility and Agency in the Acquisition of Materiality
Mary C. Gilly, University of California Irvine, USA
Stephanie Dellande, Menlo College, USA
Russell Nelson, Northwestern University, USA

Paper #2: Retailscapes as Structures of Common Difference: How Materiality Shapes Global Markets and Local Communities
Hope Jensen Schau, University of Arizona, USA
Rodrigo Costa Segabinazzi, Escola Superior de Propaganda e Marketing, Brazil
Melissa Archpru Akaka, University of Denver, USA

Kivalina E. Grove, University of Oregon, USA
Linda L. Price, University of Oregon, USA

Paper #4: Supply Money Can’t Buy: Transcendent Consumer Experiences through Living Organ Donation
Tonya Williams Bradford, University of California Irvine, USA
This Session is Fake News: The Impact of Fake News and Political Polarization on Media and Attitude Change, and Strategies for Societal Intervention

Chair: Fausto J. Gonzalez, New York University, USA

Paper #1: Opposite Partisan Perspective-Taking Leads to Polarized Assessments of Political News Truth
Fausto J. Gonzalez, New York University, USA
Minah H. Jung, New York University, USA
Clayton R. Critcher, University of California, Berkeley, USA

Paper #2: Perspective-Taking and Self-Persuasion: Why “Putting Yourself in Their Shoes” Reduces Openness to Attitude Change
Rhia Catapano, Stanford University, USA
Zakary Tormala, Stanford University, USA
Derek Rucker, Northwestern University, USA

Paper #3: Leveraging Care/Harm Moral Foundation Among Liberals and Conservatives to Reduce the Dissemination of Fake News
Hyerin Han, University of Minnesota, USA
Hyun Euh, University of Minnesota, USA
TzuShuo Ryan Wang, University of Minnesota, USA
Akshay R. Rao, University of Minnesota, USA

Paper #4: Fighting Misinformation on Social Media Using Crowdsourced Judgments of News Source Quality
Gordon Pennycook, University of Regina, USA
David Rand, Massachusetts Institute of Technology, USA

Narrative Consumption: How Stories Transmit Wisdom

Chairs: Anne Hamby, Boise State University, USA
Matthew Farmer, University of Arizona, USA

Paper #1: Story Symbols: How Meaningful Stories Enhance the Value of Story-Connected Objects
Anne Hamby, Boise State, USA
Ali Tezer, HEC Montreal, Canada
Jennifer Escalas, Vanderbilt University, USA

Alice Wang, University of Iowa, USA
Jennifer Escalas, Vanderbilt University, USA

Paper #3: Navigating Narratives: Time and Space Navigation and Narrative Experiences
Stephanie Feiereisen, Montpellier Business School, France
Dina Rasolofoarison, Paris Dauphine University, France
Cristel Russell, Pepperdine University, USA
Hope Schau, University of Arizona, USA

Paper #4: Moved by Scary Stories: How Fear Drives Narrative Transportation
Matthew Farmer, University of Arizona, USA
Jesper H. Nielsen, University of Arizona, USA

Self-Conscious Emotions: Characteristics, Coping Strategies, and Consequences

Chairs: Yan Zhang, National University of Singapore, Singapore
Xiuping Li, National University of Singapore, Singapore

Paper #1: The Self-Conscious Consumer: Understanding and Mitigating Consumer Embarrassment
Kelly B. Herd, University of Connecticut, USA
Nilufer Z. Aydinoglu, Koc University, Turkey
Aradhna Krishna, University of Michigan, USA

Paper #2: To Show Off or To Shy Away: The Effect of Self-Conscious Emotions on Self-Checkout Usage
Leonard Lee, National University of Singapore, Singapore
Yih Hwai Lee, National University of Singapore, Singapore
Xiuping Li, National University of Singapore, Singapore
Yan Zhang, National University of Singapore, Singapore
Chong Juin Kuan, National University of Singapore, Singapore

Paper #3: The Fighter and the Caregiver: Brands that Help Individuals with Self-Esteem and Social Exclusion Threats
Aulona Ulqinaku, University of Leeds, UK
Gülen Sarial-Abi, Bocconi University, Italy
J. Jeffrey Inman, University of Pittsburgh, USA

Paper #4: Attitudes Based on Feelings: Fixed or Fleeting?
Matthew D. Rocklage, Northeastern University, USA
Andrew L. Luttrell, Ball State University, USA
## Table of Contents

### We Can “Feel” the Presence: Persuasion Dynamics of Technology-Mediated Social Presence in Consumer-Firm Interactions

**Chairs:** Ana Valenzuela, Baruch College, USA
Christian Hildebrand, University of Geneva, Switzerland

**Paper #1: Detrimental Trust in Automation: How Conversational Robo Advisors Leverage Trust and Mis-Calibrated Risk Taking**
Christian Hildebrand, University of Geneva, Switzerland
Anouk Bergner, University of St. Gallen, Switzerland

**Paper #2: Getting Personal in Public? How Consumers Respond to Public Personalized Advertisements**
Nicole Jasmin Heß, Ludwig-Maximilians-University of Munich, Germany
Corinne M Kelley, Florida State University, USA
Maura Scott, Florida State University, USA
Jan Schumann, University of Passau, Germany
Martin Mende, Florida State University, USA

**Paper #3: Distant Connection: Differences in Prosocial Behavior Across Computing Devices**
Caglar Irmak, University of Miami, USA
Claudia Townsend, University of Miami, USA
Ben Bornstein, University of Miami, USA

**Paper #4: The Persuasive Power of Online Social Presence**
Rahi Hosseini, Pompeu Fabra University, Spain
Maria Galli, ESADE Business School, Spain
Ana Valenzuela, Baruch College, USA

### Moving Away from Market Creation: Examining the Growth of Aesthetic Markets

**Chair:** Pierre-Yann Dolbec, Concordia University, Canada

**Paper #1: The Politication of Objects: Meaning Making and Materiality in the US Cannabis Market**
Aimee Huff, Oregon State University, USA
Ashlee Humphreys, Northwestern University - Medill, USA
Sarah JS Wilner, Wilfrid Laurier University, Canada

**Paper #2: Collaborative Market Driving: Conceptualizing Collective Action in Market Orientation Strategies**
Andre F. Maciel, University of Nebraska-Lincoln, USA
Eileen Fischer, York University, Canada

**Paper #3: Market Aestheticization: How Markets Grow Through Value Chain Complexification**
Pierre-Yann Dolbec, Concordia University, Canada
Zeynep Arsel, Concordia University, Canada
Aya Aboelenien, Concordia University, Canada

**Paper #4: Practice Ecosystems: From Consumer Practice Disruption to Market Reinvention**
Matthew Godfrey, University of Arizona, USA
Linda L Price, University of Oregon, USA

### Understanding the Mechanisms and Outcomes of Intensive Marketization

**Chairs:** Anil Isisag, University of Wisconsin - Madison, USA
Ankita Kumar, Bucknell University, USA

**Paper #1: Mobile Dating Apps and the Intensive Marketization of Dating: Gamification as a Marketizing Apparatus**
Anil Isisag, University of Wisconsin - Madison, USA

**Paper #2: Marketization of Care: How Consumers Navigate the Commoditized Eldercare Services Market**
Ankita Kumar, Bucknell University, USA

Elodie Juge, University of Lille, France
Isabelle Collin-Lachaud, University of Lille, France
Anissa Pomies, Emlyon Business School, France

**Paper #4: Relating Americans’ Responses to the Marketization of Armed Self-Defense to Their Understandings of the Second Amendment**
Michelle Barnhart, Oregon State University, USA
Aimee Huff, Oregon State University, USA
Inara Scott, Oregon State University, USA
Mental Health and Consumer Behavior

Chair: Cristel Russell, Pepperdine University, USA
Ronald Paul Hill, American University, USA

Paper #1: Post-Traumatic Stress and Consumption Behaviors
Cristel Russell, Pepperdine University, USA
Dale W. Russell, Uniformed Services University, USA
Ronald Paul Hill, American University, USA

Paper #2: Discourses of Disability: Building Physical and Mental Marketplace Resilience
Samantha Cross, Iowa State University, USA
Akon Epko, Rutgers University, USA

Paper #3: Promoting Consumer Mental Wellness Through Emotion Regulation Strategies
Elyria Kemp, University of New Orleans, USA
My Bui, Loyola Marymount University, USA

New Directions in Hedonic and Utilitarian Consumption

Chair: Uzma Khan, University of Miami, USA
Colton Pond, University of Miami, USA

Paper #1: Role of Hedonic Choices in Sequential Decision-Making
Uzma Khan, University of Miami, USA
Colton Pond, University of Miami, USA
Ravi Dhar, Yale University, USA

Paper #2: The Effect of a Temporal Separation Between Choosing and Buying on Purchase Incidence
Gabriela N. Tonietto, Rutgers University, USA
Selin A. Malkoc, The Ohio State University, USA
Stephen M. Nowlis, Washington University in St. Louis, USA
Zhenling Jiang, Washington University in St. Louis, USA

Paper #3: Influence of Hedonic versus Utilitarian Framing on Donation Behavior
Shelly Rathee, University of Utah, USA
Arun Mishra, University of Utah, USA
Himanshu Mishra, University of Utah, USA

Paper #4: The Effect of Anticipating Regret and Satisfaction on Hedonic vs. Utilitarian Choice
Eunice Kim, Pennsylvania State University, USA
Min Zhao, Boston College, USA

How Could You Do That?!
Consumers’ Differential Reactions to Companies Treating Others Badly...or Better

Chair: Nari Yoon, Indiana University, USA
Jenny G. Olson, Indiana University, USA

Paper #1: Brand Perceptions and Consumer Support in the Face of a Transgression: Warmth Over Competence
Summer Hyoyeon Kim, University of Kansas, USA
Yexin Jessica Li, University of Kansas, USA
Jenny G. Olson, Indiana University, USA
Shailendra P. Jain, University of Washington, USA

Paper #2: Putting the Harm Back into Product-Harm: Vulnerable Social Groups, Harm Perceptions, and Consumer Complaining Behavior
Steven Shepherd, Oklahoma State University, USA
Alysson E. Light, University of the Sciences, USA

Andrea Kähr, University of Bern, Switzerland
Bettina Nyffenegger, University of Bern, Switzerland
Mansur Khamitov, Nanyang Technological University, Singapore
Harley Krohmer, University of Bern, Switzerland
Wayne D. Hoyer, University of Texas at Austin, USA

Paper #4: Should I Stay or Should I Go: When Our Companies Have Eyes for Other Consumers
Nari Yoon, Indiana University, USA
Jenny G. Olson, Indiana University, USA
Adam Duhachek, Indiana University, USA
Waste Not! Antecedents and Consequences of Disposal Decisions

Chairs: Jeehye Christine Kim, Hong Kong University of Science and Technology, China
Young Eun Huh, Korea Advanced Institute of Science and Technology, South Korea

Paper #1: Expiration Date Perception and Food Disposal Decision
Jeehye Christine Kim, Hong Kong University of Science and Technology, China
Young Eun Huh, Korea Advanced Institute of Science and Technology, South Korea

Paper #2: Stating the Obvious: How “Ugly” Labels Can Increase Purchase of Unappealing Produce and Reduce Waste
Sid Mookerjee, Sauder School of Business, University of British Columbia, Canada
Yann Cornil, Sauder School of Business, University of British Columbia, Canada
Joandrea (Joey) Hoegg, Sauder School of Business, University of British Columbia, Canada

Paper #3: Symbolic Disposal
Aaron R. Brough, Utah State University, USA
Mathew S. Isaac, Seattle University, USA

Paper #4: Rediscovering Consumer Wastefulness
Saurabh Rawal, University of Alberta, Canada
Robert Fisher, University of Alberta, Canada
Jennifer Argo, University of Alberta, Canada

“Mental Accounting Matters”:
Mental Accounting Shapes How People Invest, Spend, Purchase, and Consume

Chair: Jinwoo Kim, Carnegie Mellon University, USA

Paper #1: Moderators of Loss-Chasing: How Skewness, Information, and Framing Shape the Dynamics of Risk-Taking
Jinwoo Kim, Carnegie Mellon University, USA
Alex Imas, Carnegie Mellon University, USA
Christopher Olivola, Carnegie Mellon University, USA

Paper #2: The Effects of Earmarking on Psychological Spending and Pain of Payment
Justin N. Pomerance, University of Colorado Boulder, USA
Nicholas Reinholtz, University of Colorado Boulder, USA
Stephen Spiller, University of California, Los Angeles, USA
Elizabeth Webb, Columbia University, USA

Paper #3: Avoiding a Discount to Pay the Full Price: Contingent Promotions Backfire When Redemption is Unlikely
Andong Cheng, University of Delaware, USA
Ashley Stadler-Blank, Xavier University, USA

Paper #4: Moderators and Extensions of the Interpersonal Sunk-Cost Effect
Christopher Olivola, Carnegie Mellon University, USA
Jinwoo Kim, Carnegie Mellon University, USA
Einav Hart, University of Pennsylvania, USA

Discrete vs. Connected: How the Mental Representation of Time Impacts Goal Pursuit and Goal Fulfillment

Chair: Yanliu Huang, Drexel University, USA

Paper #1: Self-Regulation and Consumer Impatience
Hyoje (Jay) Kim, Queensland University of Technology, Australia
Hyun Seung Jin, Queensland University of Technology, Australia
Chris Janiszewski, University of Florida, USA
Clinton S. Weeks, Queensland University of Technology, Australia
Amanda T. Beatson, Queensland University of Technology, Australia

Paper #2: Counting Time by Moments: The Effect of Photo Engagement on Goals
Kristen Duke, UC San Diego, USA
Wendy Liu, UC San Diego, USA

Paper #3: Spending Gained Time
Selin A. Malkoc, The Ohio State University, USA
Gabriela Tonietto, Rutgers University, USA

Paper #4: Helping Me See the Whole Picture: How Using a Paper versus Mobile Calendar Influences Consumer Planning and Plan Fulfillment
Yanliu Huang, Drexel University, USA
Zhen Yang, Creighton University, USA
Vicki Morwitz, Columbia University, USA
Advances in Consumer Research (Volume 47) / xxi

Persuasion 2.0
Chair: Francesca Valsesia, University of Washington, USA

Paper #1: The Opportunities and Limitations of Using Virtual Reality in Charitable Appeals
Kirk Kristofferson, Ivey Business School, Canada
Michelle Daniels, Arizona State University, USA
Andrea Morales, Arizona State University, USA

Paper #2: Persuading the Bystander
Francesca Valsesia, University of Washington, USA
Kristin Diehl, University of Southern California, USA
Joseph C. Nunes, University of Southern California, USA

Paper #3: Changes to Clicks: References to Change Break Through the Clutter and Promote Persuasion
Daniella Kupor, Boston University, USA
Jayson Jia, University of Hong Kong, Hong Kong
Zakary Tormala, Stanford University, USA

Paper #4: Risk and the Rivalry Mindset: Promotions Involving Group Rivalries Increase Risky Consumption Behaviors
John P. Costello, Ohio State University, USA
Rebecca Walker Reczek, Ohio State University, USA
Robert W. Smith, Ohio State University, USA

Whether, When and Why Self-Connections to Possessions Affect Owner Decisions in the Marketplace
Chair: Antje Graul, Utah State University, USA

Paper #1: Object History Value Shapes Owner Decisions in the Sharing Economy
Charis Li, University of Florida, USA
Chris Janiszewski, University of Florida, USA

Paper #2: Do Owners in a Consumer-to-Consumer Market Ever Prefer Renting to Less-Engaged Users?
Antje Graul, Utah State University, USA
Aaron R. Brough, Utah State University, USA
Mathew S. Isaac, Seattle University, USA

Paper #3: A Little Piece of Me: When Mortality Reminders Lead to Possession Donation
Lea Dunn, University of Washington, USA
Katherine White, University of British Columbia, Canada
Darren W. Dahl, University of British Columbia, Canada

Paper #4: Identities Without Products: Can Choice about Self-Linked Possessions be Attachment-Free?
Liad Weiss, University of Wisconsin-Madison, USA

Reexamining Complexity: Dimensionality and Information Density in Consumer Decision Making
Chair: Nicholas Light, University of Colorado Boulder, USA

Paper #1: Keep It Simple (Sometimes): Consumer Perceptions of Brand Simplicity and Risk
Nicholas Light, University of Colorado Boulder, USA
Philip Fernbach, University of Colorado Boulder, USA

Paper #2: Using Consumers’ Representation of Brands to Understand which Changes Disrupt Identity
Stephanie Chen, London Business School, UK
Oleg Urminsky, University of Chicago, USA

Paper #3: When Shrouded Prices Seem Transparent: A Preference for Costly Complexity
Shannon White, University of Chicago, USA
Abigail Sussman, University of Chicago, USA
Dustin Beckett, Consumer Financial Protection Bureau, USA

Paper #4: Low Complexity Drives Similarity Judgments within Sets of Stimuli
Ellen Evers, University of California Berkeley, USA
Alexander Park, Washington University in St. Louis, USA
Daniel Lakens, Technical University Eindhoven, Netherlands
Designing Better Practices of New Technology

Chairs: Gita V. Johar, Columbia University, USA
       Byung Cheol Lee, Columbia University, USA

Paper #1: (No) Privacy Please: Power Distance Beliefs and Response to Privacy Breaches
       Shilpa Madan, Columbia University, USA
       Krishna Savani, Nanyang Technological University, Singapore

Paper #2: Time Flies...But Only When the Speed is “Just Right”: How Animation Speed Affects Perceived Waiting Time
       Yu Ding, Columbia University, USA
       Ellie J. Kyung, Dartmouth College, USA

       Phyliss J. Gai, Erasmus University, The Netherlands
       Anne-Kathrin Klesse, Erasmus University, The Netherlands

       Byung Cheol Lee, Columbia University, USA
       Gita V. Johar, Columbia University, USA

The Essence Conveyed by Origins, Creators and Products: How Consumers Perceive Value

Chairs: Rashmi Adaval, University of Cincinnati, USA
       Ravi Dhar, Yale University, USA

Paper #1: The Role of Origins and Essence in Heritage Branding
       Nathanael Martin, University of Cincinnati, USA
       T. Andrew Poehlman, Clemson University, USA
       Noah VanBergen, University of Cincinnati, USA

Paper #2: How Solitude Helps Essence Retention and Increases Demand for a Creator’s Product
       Suhas Vijayakumar, Hong Kong University of Science and Technology, Hong Kong, SAR China
       Wooyun Yang, Hong Kong University of Science and Technology, Hong Kong, SAR China
       Rashmi Adaval, University of Cincinnati, USA

Paper #3: When Heritage Branding Limits Consumer Desire for Innovation
       Rosanna K. Smith, University of Georgia, USA
       Minju Han, Yale University, USA
       George E. Newman, Yale University, USA
       Ravi Dhar, Yale University, USA

Paper #4: Preserving Essence: The Mere Packaging Effect
       Tim Doering, University of Michigan, USA
       Katherine Burson, University of Michigan, USA
       Andrew Gershoff, University of Texas at Austin, USA

New Wine in Old Glasses: Influencing Judgments Through Sound, Sight, and Semantics

Chair: Johann Melzner, New York University, USA

Paper #1: The Sound of Music: The Influence of Timbre on Product Perception
       Johann Melzner, New York University, USA
       Priya Raghupur, New York University, USA

       Luca Cian, University of Virginia, USA
       Chiara Longoni, Boston University, USA
       Aradhna Krishna, University of Michigan, USA

Paper #3: Do Firm Cues Impact Product Perceptions?: When Small is Natural
       Ana Scekic, HEC Paris, France
       Aradhna Krishna, University of Michigan, USA

Paper #4: Perceptual Grounding of Quantity
       Arnaud Monnier, Cornell University, USA
       Manoj Thomas, Cornell University, USA
Time Matters: Dynamics of Sequential and Simultaneous Multiple Goal Pursuit

Chair: Sarah Memmi, Duke University, USA

Paper #1: Budgeting Time First Increases Multiple Goal Achievement
Sarah A. Memmi, Duke University, USA
Jordan Etkin, Duke University, USA

Paper #2: Planning for Multiple Shopping Goals in the Marketplace
Jacob Suher, Portland State University, USA
Szu-chi Huang, Stanford University, USA
Leonard Lee, National University of Singapore, Singapore

Paper #3: The Better Path Not Taken: Goal-Setting Undermines Opportunity Cost Consideration
Liz Friedman, Yale University, USA
Minju Han, Yale University, USA
Guy Voichek, Yale University, USA
Ravi Dhar, Yale University, USA

Paper #4: A Multi-Goal Approach to Food Consumption: How Food Restrictions Affect Social-Relationship Goals
Kaitlin Woolley, Cornell University, USA
Ayelet Fishbach, University of Chicago, USA
Michelle Wang, Cornell University, USA

Getting Wiser? New Insights into Consumer Research Practices

Chairs: Antonia Krefeld-Schwalb, University of Geneva, Switzerland
Gabriele Paolacci, Erasmus University Rotterdam, The Netherlands
Benjamin Scheibehenne, University of Geneva, Switzerland

Paper #1: Using P-Curve to Assess Evidentiary Value from 10 Years of Published Literature
Leif Nelson, University of California, Berkeley, USA
Fausto Gonzalez, New York University, USA
Michael O’Donnell, Georgetown University, USA
Hannah Perfecto, Washington University in St. Louis, USA

Paper #2: 99% Impossible: A Valid, or Falsifiable, Internal Meta-Analysis.
Joachim Vosgerau, Bocconi University, Italy
Uri Simonsohn, ESADE, USA
Leif D. Nelson, University of California Berkeley, USA
Joseph Simmons, Wharton School, USA

Paper #3: The Price of Behavioral Research
Jason Roos, Erasmus University Rotterdam, The Netherlands
Gabriele Paolacci, Erasmus University Rotterdam, The Netherlands

Antonia Krefeld-Schwalb, University of Geneva, Switzerland
Benjamin Scheibehenne, University of Geneva, Switzerland

Leveraging New Technologies in Marketing: Its Limitations and Opportunities

Chair: Shwetha Mariadassou, Stanford University, USA

Paper #1: Augmented Reality Dissected: Decoupling the Visual and Interactive Elements of AR in Encouraging Consumers to Read Food Reviews
Jen H. Park, Stanford University, USA
Szu-chi Huang, Stanford University, USA

Paper #2: When Virtual Reality Backfires on Reality: VR Reduces High Sensation Seekers’ Desire for Stimulation
Youjung Jun, Columbia University, USA
Jae Jaeyeon Chung, Rice University, USA
Gita Johar, Columbia University, USA

Shwetha Mariadassou, Stanford University, USA
Christopher J. Bechler, Stanford University, USA
Jonathan Levav, Stanford University, USA

Paper #4: Should I Give Siri my Credit Card? How Mode of Interaction Affects Willingness to Share Personal Information with Machines
Juliana Schroeder, University of California, Berkeley, USA
Matthew Schroeder, Facebook, USA
# Table of Contents

**Influences of Numerical and Scale Formats on Judgments**

*Chair: Christopher J. Bechler, Stanford University, USA*

**Paper #1: Placing Value on Place Value: Numerical Precision Influences the Weighting of Ascending versus Descending Attributes**  
Jorge Pena Marin, University of Cincinnati, USA  
Mathew S. Isaac, Seattle University, USA

**Paper #2: Consumers Perceive That Whole-Number Average Ratings Reflect Less Variable Distributions**  
Christopher J. Bechler, Stanford University, USA  
Jonathan Levav, Stanford University, USA  
Joshua I. Morris, Stanford University, USA

**Paper #3: The Commission Effect**  
Mathew S. Isaac, Seattle University, USA  
Julio Sevilla, University of Georgia, USA  
Rajesh Bagchi, Virginia Tech, USA

**Paper #4: Left-Right or Top-Down? The Effect of Horizontal versus Vertical Scale Orientation on Consumer Judgments**  
Ellie Kyung, Dartmouth College, USA  
Manoj Thomas, Cornell University, USA  
Aradhna Krishna, University of Michigan, USA

**Word of Mouth: Emerging Insights and New Directions for Consumer Research**

*Chairs: Christopher J. Bechler, Stanford University, USA  
Zakary L. Tormala, Stanford University, USA*

**Paper #1: Sharing Like a Boss: How a Consumer’s Position in the Hierarchy Influences Word-of-Mouth Valence**  
Christielle du Plessis, Singapore Management University, Singapore  
Michael Schraer, Singapore Management University, Singapore  
David Dubois, INSEAD, France

**Paper #2: Choosing Targets: How Expectations of Qualitative Change Influence Word of Mouth**  
Christopher J. Bechler, Stanford University, USA  
Zakary L. Tormala, Stanford University, USA  
Derek D. Rucker, Northwestern University, USA

Carter Morgan, University of Miami, USA  
Zoey Chen, University of Miami, USA  
Sara Loughran Dommer, Georgia Institute of Technology, USA

**Paper #4: Word of Mouth: A Review and Directions for Future Work**  
Jonah Berger, Wharton School of the University of Pennsylvania, USA

**Wise and Foolish Consumer Financial Decisions**

*Chair: Kellen Mrkva, Columbia University, USA*

**Paper #1: A Structural Test of Mental Accounting and Consumer Fungibility From Credit Card Expenditures**  
Nicholas Pretnar, Carnegie Mellon University, USA  
Christopher Olivola, Carnegie Mellon University, USA  
Alan Montgomery, Carnegie Mellon University, USA

**Paper #2: Minimum Payments Alter Debt Repayment Strategies Across Multiple Credit Cards**  
Abigail Sassman, University of Chicago, USA  
Samuel Hirshman, University of Chicago, USA

**Paper #3: Searching, Fast and Slow: How Time Preferences Influence Credit Card Search and Choice**  
Kellen Mrkva, Columbia University, USA  
Elizabeth C Webb, Columbia University, USA  
Eric J Johnson, Columbia University, USA

**Paper #4: An Under-Shooting Bias in Asymmetric Resource Problems**  
Christopher Hsee, University of Chicago, USA  
Xilin Li, University of Chicago, USA  
Ying Zeng, University of Chicago, USA  
Alex Imas, Carnegie Mellon University, USA
Understanding More About Having Less: Consumer Responses to Scarcity

Chair: Wooyun Yang, Hong Kong University of Science and Technology, Hong Kong, SAR China

Paper #1: Resource Scarcity Enhances the Value of Pride
Anthony Salerno, University of Cincinnati, USA
Brianna Escoe, University of Cincinnati, USA

Paper #2: My Voice Also Counts: Financial Scarcity Shapes Attitude Extremity Through a Heightened Need to be Heard
Wooyun Yang, Hong Kong University of Science and Technology, Hong Kong, SAR China
Jeehye Christine Kim, Hong Kong University of Science and Technology, Hong Kong, SAR China
Rashmi Adaval, University of Cincinnati, USA

Paper #3: Reminders of Resource Scarcity Decrease State Social Self-esteem and Increase the Desire for Self-Improvement Products
Ali Tezer, HEC Montréal, Canada
Caroline Rous, Concordia University, Canada
Kelly Goldsmith, Vanderbilt University, USA

Paper #4: Impact of Product Supply Level on Choice Switching
Yuechen Wu, Johns Hopkins University, USA
Meng Zhu, Johns Hopkins University, USA
Rebecca Ratner, University of Maryland, USA

Chair: Ana Valenzuela, Baruch College, USA

Paper #1: You Can’t be Too Polite, Alexa! Implied Politeness of Mechanized Auditory Feedback and Its Impact on Perceived Performance Accuracy
Eda Sayin, IE Business School, IE University, Spain
Adhuna Krishna, University of Michigan, USA

Paper #2: Her Too: Consumers Express Greater Frustration and Aggression With Female Artificial Intelligence
Rhonda Hadi, Oxford University, UK
Lauren Block, Baruch College, USA

Paper #3: Minds vs. Machines: Investigating the Role of Anthropomorphism on Knowledge Misattributions in Voice-Activated Consumer Search
Kristy Hamilton, University of Illinois at Urbana-Champaign, USA
Adrian Ward, University of Texas at Austin, USA
Mike Yao, University of Illinois at Urbana-Champaign, USA

Paper #4: The Verbal Chameleon Effect, and Alexa. An Assemblage Theory Approach
Ana Valenzuela, Baruch College, USA
David Luna, University of Central Florida, USA
Jessie Du, Baruch College, USA

Promise and Perils for Agency in Technology Augmentation

Chairs: Ashok Kumar Kaliyamurthy, University of Arizona, USA
Hope Jensen Schau, University of Arizona, USA

Paper #1: The Double-Edged Sword of Online Collective Deal Creation
Hope Schau, University of Arizona, USA
Colin Campbell, University of San Diego, USA

Paper #2: Managing For Me, Myself, and AI: Why Mythology Hurts AI Investments
Simona Botti, London Business School, UK
Markus Giesler, York University, Canada
Stefano Puntoni, Erasmus University Rotterdam, The Netherlands
Rebecca Walker Reczek, Ohio State University, USA

Paper #3: Quantification, Algorithms and Agency
Ashok Kumar Kaliyamurthy, University of Arizona, USA
Ignacio Luri, University of Arizona, USA
Hope Schau, University of Arizona, USA

Paper #4: Benevolent Surveillance? Enhancing Efficiency and Employee Safety With AI
Sarah Lord Ferguson, Simon Fraser University, Canada
Emily Lord Treen, Simon Fraser University, Canada
Leyland Lord Pitt, Simon Fraser University, Canada
Jan Kietzmann, University of Victoria, Canada
When Marketing Alienates Consumers ................................................................. 254
Chair: Klaus Wertenbroch, INSEAD, Singapore

Paper #1: The Dark Side of Microtargeting: Predicting Consumers’ Preferences Threatens Their Sense of Free Will
Rom Schrift, University of Pennsylvania, USA
Klaus Wertenbroch, INSEAD, Singapore
Yonat Zwebner, Interdisciplinary Center (IDC), USA

Paper #2: Calculators for Women: When Identity Appeals Provoke Backlash
Tami Kim, University of Virginia, USA
Leslie John, Harvard Business School, USA
Kate Barasz, IESE, Spain
Mike Norton, Harvard Business School, USA

Paper #3: The Dematerialization of Consumption
Maria Cristina Cito, Bocconi University, Italy
Eugina Leung, Erasmus University, The Netherlands
Gabriele Paolacci, Erasmus University, The Netherlands
Stefano Puntoni, Erasmus University, The Netherlands

Paper #4: The Signature Effect: How Personizing the Fruits of One’s Labor Increases Work Motivation and Performance
Ulrike Kaiser, WU Vienna, Austria
Martin Schreier, WU Vienna, Austria
Christoph Fuchs, Technical University Munich, Germany
Stijn van Osselaer, Cornell University, USA

The Machine Age of Consumer Research:
How Robot-Based Expression Modalities Alter Perception and Choice. .......................... 259
Chair: Christian Hildebrand, University of St. Gallen, Switzerland

Paper #1: Mistaking Minds and Machines: How Speech Affects Dehumanization and Anthropomorphism
Juliana Schroeder, University of California Berkeley, USA
Nicholas Epley, University of Chicago, USA

Paper #2: Robot or Human? How Bodies and Minds Shape Consumer Reactions to Human-Like Robots
Noah Castelo, University of Alberta, Canada
Bernd Schmitt, Columbia University, USA
Miklos Sarvary, Columbia University, USA

Paper #3: Conversational Interfaces as Persuasion Instruments: Implications for Consumer Choice and Brand Perceptions
Anouk Bergner, University of St. Gallen, Switzerland
Christian Hildebrand, University of St. Gallen, Switzerland
Gerald Häubl, University of Alberta, Canada

Paper #4: Blaming the Bot: Anthropomorphism Exacerbates Negative Responses from Angry Customers
Rhonda Hadi, University of Oxford, UK
Cammy Crolic, University of Oxford, UK
Felipe Thomaz, University of Oxford, UK
Andrew Stephen, University of Oxford, UK
How Would You Like to Pay for That?  
The Effect of Payment Method on Consumer Behavior

Chair: Daniel Katz, University of Chicago, USA

Paper #1: Increasing the Pain of Payment Increases Affiliation and Rapport in Collaborative but not Competitive Relationships
Avin Shah, University of Toronto, Canada
James R. Bettman, Duke University, USA
Tanya L. Chardran, Duke University, USA
Kathleen D. Voocks, University of Minnesota, USA

Paper #2: Not all Debt is Created Equal: On the Mental Accounting of Debt Forms
Eesha Sharma, Dartmouth College, USA
Stephanie Tully, Stanford University, USA
Cynthia Cryder, University of Washington in St. Louis, USA

Paper #3: The Impact of Payment Plans on Feelings of Financial Constraint
Christina Kan, Texas A&M University, USA
Daniel Katz, University of Chicago, USA
Abigail Sussman, University of Chicago, USA

Christopher J. Bechler, Stanford University, USA
Joshua I. Morris, Stanford University, USA
Szu-chie Huang, Stanford University, USA

Wising Up About Goal Progress:
The Antecedents and Consequences of Goal Progress Perceptions

Chairs: Marissa Sharif, University of Pennsylvania, USA
Kaitlin Woolley, Cornell University, USA

Paper #1: The Categorization Bias: The Effect of Categorization on Goal Progress Perceptions and Motivation
Marissa Sharif, University of Pennsylvania, USA
Kaitlin Woolley, Cornell University, USA

Paper #2: The Difficulty of Task Initiation Affects Consumers’ Perceived Goal Progress
Hoori Rafieian, Drexel University, USA
Marissa Sharif, University of Pennsylvania, USA

Paper #3: Moderating the Progress Bias: The Role of Goal Orientation
Margaret C. Campbell, University of Colorado, USA
Justin Pomerance, University of Colorado, USA
Caleb Warren, University of Arizona, USA

Paper #4: Looking Back on a Journey to Derive Growth: Using Conceptual Metaphor to Shape Perceptions of an Attained Goal
Szu-chie Huang, Stanford University, USA
Jennifer Aaker, Stanford University, USA

There is More to Promotions Than Increased Sales:
Novel Consumer Responses to In-Store Promotions

Chairs: Chaumanix Dutton, University of Southern California, USA
Kristin Diehl, University of Southern California, USA

Paper #1: When is HILO Low? Price Image Formation Based on Frequency versus Depth Pricing Strategies
Daniel Sheehan, University of Kentucky, USA
Ryan Hamilton, Emory University, USA
Ramnath K. Chellappa, Emory University, USA

Chaumanix Dutton, University of Southern California, USA
Kristin Diehl, University of Southern California, USA

Paper #3: Waiting and Watching: The Effects of Observing Others’ Point-of-Payment Prosocial Decisions
Jillian Hmurovic, University of Pittsburgh, USA
Cait Lambert, University of Pittsburgh, USA

Paper #4: Can Featuring Social Media Photographs of In-Store Retail Events Cause FOMO?
Jacqueline R. Rijkin, Duke University, USA
Cindy Chan, University of Toronto, Canada
Barbara E. Kahn, University of Pennsylvania, USA
Biases in Consumer Money Management .......................... 281
Chair: Byung Cheol Lee, Columbia University, USA

Paper #1: The Role of Attention in Opportunity Cost Neglect
Stephanie Smith, Ohio State University, USA
Stephen A Spiller, University of California Los Angeles, USA
Ian Krajbich, Ohio State University, USA

Paper #2: When $5 is Not $5: Search Strategies and Relative Thinking about Money
Byung Cheol Lee, Columbia University, USA
Crystal Reeck, Temple University, USA
Eric J Johnson, Columbia University, USA

Paper #3: Source, Form, and Form of the Source: A Malleable Monopoly Money Phenomena
Priya Raghubir, New York University, USA
Shelle Santana, Harvard Business School, USA

Paper #4: Beliefs about Future Wealth Impact Financial Decisions
Jennifer Trueblood, Vanderbilt University, USA
Abigail Sussman, University of Chicago, USA

Living in a Socially Connected World:
The Impact of Others’ Face-to-Face and Virtual Presence on Consumer Behavior .................. 286
Chairs: Yanping Tu, University of Florida, USA
Szu-chi Huang, Stanford University, USA

Paper #1: The Curvilinear Effect of Crowdedness on Consumer Misbehavior
Camilla Song, University of Florida, USA
Yanping Tu, University of Florida, USA
Szu-chi Huang, Stanford University, USA

Paper #2: Graded and Context-Dependent Technology Associations: Why Using a Smartphone Can Signal Both
More and Less Social Connection
Ann E. Schlosser, University of Washington, Seattle, USA
Rebecca W. Hamilton, Georgetown University, USA

Paper #3: Feeling Bad for the Brand: Encouraging Positive Consumer Reactions to Unfair Negative Reviews
through Empathetic Responding
Thomas Allard, Nanyang Technological University, Singapore
Lea H. Dunn, University of Washington, USA
Katherine White, University of British Columbia, Canada

Paper #4: The Impact of Feedback on Recommendations: What Happens When Others Dislike the Recommendation
Virginia Weber, Deakin University, Australia
Jennifer Argo, University of Alberta, Canada
Sarah Moore, University of Alberta, Canada

Helping Consumers Make Wise Choices About Food .................. 291
Chair: Holly Howe, Duke University, USA

Paper #1: Would You Like Fries With That? Modeling the Default Effect in Dietary Choice
Nicolette Sullivan, Duke University, USA
Samyukta Doré, Duke University, USA
Alexander Breslav, Duke University, USA
Scott Huettel, Duke University, USA

Paper #2: Sacrifices Must be Made: The Preference for Trading Off Type or Quantity Among Restrained Versus
Unrestrained Eaters
Peggy Liu, University of Pittsburgh, USA
Kelly Haws, Vanderbilt University, USA

Paper #3: Using a Novel Online Grocery Platform to Explore How Front-of-Package Labelling Affects Consumers’
Food Choice
Holly S Howe, Duke University, USA
Gavan Fitzsimons, Duke University, USA
Peter Ubel, Duke University, USA

Paper #4: How Do Nutrition Promotions Impact Shoppers’ Sensitivity to Price Promotions?
Meheli Basu, University of Pittsburgh, USA
Hristina Nikolova, Boston College, USA
Jeff Inman, University of Pittsburgh, USA
Understanding Co-Creation:
Re-examining Value and Experience in Consumer Research ........................................... 297
Chairs: D. Matthew Godfrey, University of Massachusetts Amherst, USA
Nathan B. Warren, University of Oregon, USA

Paper #1: Co-Creating Neighborhood Brands
Meredith Rhoads Thomas, Florida State University, USA
Alex Mitchell, California State Polytechnic University, Pomona, USA

Paper #2: Trickster Consumers: Consumed by Passion
Nathan B. Warren, University of Oregon, USA
Linda L. Price, University of Oregon, USA

Paper #3: Value in Heterogeneity: How Servicescape Experiences Emerge From Divergent Consumption Practices
D. Matthew Godfrey, University of Massachusetts Amherst, USA
Melanie Wallendorf, University of Arizona, USA

Paper #4: Understanding Co-Creation Through a Playbour Lens
Annetta Grant, Bucknell University, USA
Peter A. Dacin, Queen’s University, Canada

Reconsidering the Formation and Consequences of Injustice in the Marketplace .................. 304
Chair: Broderick Turner, Northwestern University, USA

Paper #1: (Trans)Women Are Wonderful?
Broderick Turner, Northwestern University, USA
Galen V. Bodenhausen, Northwestern University, USA

Paper #2: An Increase in Interracial Marriage Increases Racial Bias
Allison Skinner, Northeastern University, USA
James Rae, University of Massachusetts, USA

Paper #3: Reach Out in the Darkness: How Unfair Treatments Shape Social Connection Motivation
Yijie Wang, Hong Kong Polytechnic University, China
Yuwei Jiang, Hong Kong Polytechnic University, China
Mandy Mantian Hu, Chinese University of Hong Kong, China
Ninghua Zhong, Tongji University, China

Paper #4: Perceptions of Your #MeToo Post: Men and Women See it Differently
Wendy De La Rosa, Stanford University, USA
Solene Delecourt, Stanford University, USA
Odyssia Ng, Stanford University, USA

Rethinking the Stability of Consumer Impatience:
How Consumer Intertemporal Preferences Vary Across........................................... 309
Chairs: Oleg Urminsky, University of Chicago, USA
Jennifer Trueblood, Vanderbilt University, USA

Paper #1: Patient For Candy or Cash? The Robustness of Impatience Across Affect-Rich and Affect-Poor Resources
Oleg Urminsky, University of Chicago, USA
Timothy Kim, University of Chicago, USA

Paper #2: The Sign Effect in Consumer Intertemporal Choice: Evidence and Explanation
David Hardisty, University of British Columbia, Canada
Elke U. Weber, Princeton University, USA

Paper #3: Thinking Fast Does Not Increase Temporal Myopia in Decision-Making
Jennifer Trueblood, Vanderbilt University, USA
Breanna Crane, Vanderbilt University, USA

Paper #4: Scarcity and Intertemporal Choice: An Integrative Framework
Eesha Sharma, Dartmouth College, USA
Stephanie Tully, University of Southern California, USA
Xiang Wang, University of Florida, USA
Post-Colonial Theory:
Consumer Empowerment through Marketplace Decolonization

Chairs: Michal Carrington, University of Melbourne, Australia
Ai Ming Chow, University of Melbourne, Australia
Julie L. Ozanne, University of Melbourne, Australia

Paper #1: Racialized Brands: A By-Product of Cultural Branding
Ela Veresiu, Schulich School of Business, York University, Canada

Paper #2: Colonial Advertising, Desubjectification, and Epidermalization of Servitude in India
Rohit Varman, University of Birmingham, UK

Ruth Rentschler, University of South Australia, Australia
Russell Belk, Schulich School of Business, York University, Canada

Paper #4: Indigenous Art Market: A Site of Cultural Production or Cultural Assimilation?
Ai Ming Chow, University of Melbourne, Australia
Michal Carrington, University of Melbourne, Australia
Julie L. Ozanne, University of Melbourne, Australia

A New Look at Beauty in Consumer Decision Making

Chair: Qin Wang, Arizona State University, USA

Paper #1: When a Beautiful Service Provider Makes Mistakes: To Forgive or Not to Forgive?
Lisa C. Wan, The Chinese University of Hong Kong, Hong Kong
Robert S. Wyer, Jr., University of Cincinnati, USA

Paper #2: Creditworthiness is in the Eye of the Beholder: How Consumers’ Own Attractiveness Shapes Generosity toward [Un]Attractive Microloan Borrowers
Rhiannon MacDonnell Mesler, University of Lethbridge (Calgary Campus), Canada
Ali Besharat, University of Denver, USA
Jennifer Argo, University of Alberta, Canada

Paper #3: The Beautified Me is Me: How Interdependence Increases Beauty App Use Intention
Qin Wang, Arizona State University, USA
Andrea C. Morales, Arizona State University, USA
Adriana Samper, Arizona State University, USA

Paper #4: Inspirational Aesthetics: How Beautiful Products Motivate Performance
Kelly Herd, University of Connecticut, USA
Page Moreau, University of Wisconsin, USA

Exploring Anthropomorphism Through the Lens of Agency and Communion

Chair: Linyun W. Yang, University of South Carolina, USA

Paper #1: When the Flu Speaks: The Effect of Disease Anthropomorphism on Protection Motivation
Lili Wang, Zhejiang University, China
Rima Touré-Tillery, Northwestern University, USA
Ann L. McGill, University of Chicago, USA

Paper #2: Products are People Too! Making Taboo Trade-Offs with Anthropomorphized Products
Jing Wan, University of Groningen, The Netherlands
Pankaj Aggarwal, University of Toronto, Canada

Paper #3: Greater Expectations: Anthropomorphic Products Must Be Warm and Competent...Or Else
Jenny G. Olson, Indiana University, USA
James A. Mourey, DePaul University, USA

Paper #4: Is Male the Default Gender? The Distinctive Effects Anthropomorphizing Products as Male versus Female
Linyun W. Yang, University of South Carolina, USA
Pankaj Aggarwal, University of Toronto, Canada
Comparisons are the Key to Context:
How Representations, Order and Evaluability Shape Context Effects .......................................................... 332
Chairs: Jennifer Trueblood, Vanderbilt University, USA
Jiaqian (Jane) Wang, University of Chicago, USA

Paper #1: “Seeing” the Attraction: The Attraction Effect in Choices Between Visual Stimuli
Jiaqian (Jane) Wang, University of Chicago, USA
Oleg Urminsky, University of Chicago Booth School of Business, USA

Paper #2: Context Effects Explained through the Accumulation of Simple Comparisons
Jennifer Trueblood, Vanderbilt University, USA
Nathan Evans, Vanderbilt University, USA and The University of Amsterdam, The Netherlands
William Holmes, Vanderbilt University, USA

Paper #3: Revisiting the Dynamics of Deferred Decisions: An Evaluability-Based View of Choice Deferral
Ioannis Evangelidis, Bocconi University, Italy
Jonathan Levav, Stanford University, USA
Itamar Simonson, Stanford University, USA

Paper #4: Distinguish Justifiability from Evaluability in Single vs. Joint Evaluation
Xilin Li, University of Chicago Booth School of Business, USA
Christopher K. Hsee, University of Chicago Booth School of Business, USA

Beliefs about the Future:
Anticipating the Quality, Controllability, and Duration of Future Experiences .................................................. 337
Chair: Kristin Donnelly, Haas School of Business, University of California, Berkeley, USA

Paper #1: Consumers Believe They Will Have More Control Over the Future than They Did Over the Past
Elanor F. Williams, Washington University in St. Louis, USA
Robyn A. LeBoeuf, Washington University in St. Louis, USA

Paper #2: Does Choice Cause an Illusion of Control?
Joowon Klusowski, University of Pennsylvania, USA
Deborah A. Small, University of Pennsylvania, USA
Joseph P. Simmons, University of Pennsylvania, USA

Paper #3: When Experiences Go Badly: The Buffering Effect of Scheduling on Dissatisfaction
Gabriela N. Tonietto, Rutgers University, USA

Paper #4: Time Periods Feel Longer When They Span More Boundaries
Kristin Donnelly, University of California, Berkeley, USA
Ellen R.K. Evers, University of California, Berkeley, USA

Growing Wise to Technology:
Understanding How Technology Affects Enjoyable Consumption ................................................................. 342
Chair: Holly S Howe, Duke University, USA

Paper #1: Understanding the Drivers of Binge-Watching
Kaitlin Woolley, Cornell University, USA
Marissa Sharif, University of Pennsylvania, USA

Paper #2: Too Much Enjoyable Information Leads to Less Enjoyment
Ke Wang, Harvard University, USA
Christopher Hsee, University of Chicago, USA

Paper #3: Doing it for the ‘Gram: Sacrificing Enjoyment When Posting Online
Holly S Howe, Duke University, USA
Jordan Etkin, Duke University, USA
Alixandra Barasch, New York University, USA

Paper #4: Preference Reversals Between Digital and Physical Goods
Fuad Adnan Shennib, Stanford University, USA
Rhia Catapano, Stanford University, USA
Jonathan Levav, Stanford University, USA
Extracting Behavioral Insights From Big Data: Novel AI and NLP Approaches .......................................................... 347
Chairs: Ming Hsu, University of California, Berkeley, USA

Na Kyong Hyan, Georgia Tech, USA
Samuel Bond, Georgia Tech, USA

1K Any Smile? Any Gender?
What Matters in Static Ads to Boost Consumers’ Product Evaluation ........................................... 975
Giuliana Isabella, Insper, Brazil
Valter Afonso Vieira, Maringá State University, Brazil

30 Who Does Evaluate Semantic Incongruent Cues Positively?
Examining the Moderating Effect of Autotelic Need For Touch .................................................... 975
Hiroaki Ishii, Seikei University, Japan
Taku Togawa, Chiba University of Commerce, Japan
Jaewoo Park, Musashi University, Japan

10D It’s a Half-Robin Hood Thing:
How Political Activism by Corporations Drives Consumers to Cheat ........................................ 975
Pradeep Jacob, Arizona State University, USA
Naomi Mandel, Arizona State University, USA

13J What’s Next? The Role of Contemporary Technology
in Shaping Consumers’ Product Discovery ...................................................................................... 975
Shahzeb Jafri, York University, Canada
Eileen Fischer, York University, Canada

9D Performing Pro-Sociality in the Face of Paradox: How do Consumers
Navigate Normative Ideologies While Participating in Prosocial Projects? ................................. 975
Shahzeb Jafri, York University, Canada
Eileen Fischer, York University, Canada

12J Effect of Online WOM (Word of Mouth) on Product Sales:
Focusing on Channel Characteristics ............................................................................................. 976
Jaihyun Jeon, Seoul National University, South Korea
Taewook Lim, Seoul National University, South Korea
Byung-do Kim, Seoul National University, South Korea
Junhee Seok, Seoul National University, South Korea

1E Skip My Empathy: Impact of Goal and Emotion
on Ad-Skipping Rate and ad Effectiveness ...................................................................................... 976
Yongwoog Andrew Jeon, University of Texas at Austin, USA
Yuhosua Ryoo, Southern Illinois University, Carbondale
Hye Jin Yoon, University of Georgia, USA

11H The Difference of Consumer Responses According to Nostalgia Type ............................... 976
Jeeyoon Jeong, Korea University, South Korea

16C The Empty Self: Addressing Dual Self-Discrepancies ............................................................. 976
You Jin (Julia) Jeong, Northwestern University, USA

7H Does Being Short Lead to Better Self-Control? ...................................................................... 976
Lei Jia, Ohio State University, USA
Xiaoyan Deng, Ohio State University, USA
Xiaojing Yang, University of South Carolina, USA

6D The Effect of Control Deprivation on Consumers’ Adoption
of No-Pain, No-Gain Principle ...................................................................................................... 976
Yanli Jia, Xiamen University, China
Robert Wyer Jr., University of Cincinnati, USA
13C When Collecting Personal Data From Consumers Backfires

Jianna Jin, Ohio State University, USA
Robert Smith, Ohio State University, USA
Rebecca Walker Reczek, Ohio State University, USA

10H Consumer Resistance: Anarchy, Anti-Capitalism and the ‘War Machine’

Hunter Jones, Aalto University, Finland
Joel Hietanen, University of Helsinki, Finland

7L Parenthood Increases Desire For Conspicuous Luxury Goods

Aziza Caimile Jones, Rutgers University, USA
Kristina Durante, Rutgers University, USA
Sarah Hill, Texas Christian University, USA
Hannah Bradshaw, Texas Christian University, USA

2B Product Line Extensions Hurts the Brand Owners: Psychological Ownership as a Mediator

Wonsuk Jung, University of Wisconsin - Madison, USA
Joann Peck, University of Wisconsin - Madison, USA
Mauricio Palmeira, Sungkyunkwan University, South Korea
Kyeongheui Kim, Sungkyunkwan University, South Korea

17D The Variation of Preference Stability in Decision-Making Across Gain and Loss Domains

Jungkeun Kim, Auckland University of Technology, New Zealand
Yuanyuan (Gina) Cui, Auckland University of Technology, New Zealand
Ryan Wang, University of Minnesota, USA
Raghunath Rao, University of Texas at Austin, USA
Akshay Rao, University of Minnesota, USA

3I Revisiting How the Elongation Bias Affects Consumer Perceptions

Dongeun Kim, University of Iowa, USA
Catherine Cole, University of Iowa, USA
Dhananjay Nayakankuppam, University of Iowa, USA
William Hedgcock, University of Minnesota, USA

19F Humanlike Underdogs: The Moderating Role of Service Type (SST vs. Face-to-Face) and Brand Status (Underdog vs. Top-Dog) on Brand Attitude

Yaeri Kim, Seoul National University, South Korea
Kiwan Park, Seoul National University, South Korea
Seojin Stacey Lee, Seoul National University, South Korea

3H Goals Come in All Shapes and Sizes: Can Goal-Shaped Products Increase Willingness-to-Pay?

Hae Joo Kim, Wilfrid Laurier University, Canada
Darlene Walsh, Concordia University, Canada
Philippe Wodnicki, Concordia University, Canada

11M Rudy the Rutabaga: How Anthropomorphic Naming Increases Purchase Intentions For Irregular Produce

Kacy Kim, Bryant University, USA
Nathan Yoon, Sharon High School, USA
Danae Manika, Newcastle University, UK

11B Where to Place Green Products?

Kacee Kim, University of Scranton, USA
Elizabeth Miller, University of Massachusetts, USA

12O I’m Proud But I’m Not Playing:

Colleen P. Kirk, New York Institute of Technology, USA
8D Emotions, Not Knowledge, Are Power: The Curios Case of Evidence Insensitive Product Rejection
Jan Andre Koch, University of Groningen, The Netherlands
Koert van Ittersum, University of Groningen, The Netherlands
Jan Willem Bolderdijk, University of Groningen, The Netherlands

5P Does Food Packaging Make Us Fat? The Mechanism of the Partitioning Paradox
Haruka Kozuka, University of Toyama, Japan

Caspar Krampe, Heinrich-Heine-University, Germany
Lasse Meißner, Heinrich-Heine-University, Germany
Nadine Gier, Heinrich-Heine-University, Germany
Peter Kenning, Heinrich-Heine-University, Germany

17K When is it a Good Time to Plan for Your Retirement? The Use of Questions to Encourage Financial Planning
Ann Kronrod, University of Massachusetts Lowell, USA

15D Self-Presentation in the Mating Market: A Cross-Cultural Analysis of Costly Signaling Behavior
Chaim Kuhnreich, Concordia University, Canada
Lilian Carvalho, FGV/EAESP
Gad Saad, Concordia University, Canada

10E Does Imagining Seeing Bad Make You Not Do Good? The Effect of Identity-Based and Product Factors on Consumer Response to Cause Marketing Offers
Katina Kulow, University of Louisville, USA
Mina Kwon, University of Louisville, USA
Mike Barone, University of Louisville, USA

Mina Kwon, University of Louisville, USA
Mike Barone, University of Louisville, USA

2K How Political Elections Impact Brand Equity
Polina Landgraf, IE Business School, IE University, Spain
Antonios Stamatiogiannakis, IE Business School, IE University, Spain
Haiyang Yang, Johns Hopkins University, USA

17N Detecting Feelings of Financial Distress from Bank Transactions
Alixe Lay, University College London, UK
Joe Gladstone, University College London, UK

17H The Dynamics of Consumers’ Over-Indebtedness
Julio Cesar Leandro, Fundação Getúlio Vargas, Brazil
Delane Botelho, EAESP-FGV, Brazil

18L The Influence of Reference-Price Ads’ Formats on Consumers’ Price Perceptions and Buying Intentions
Chao-Feng Lee, National Chung Cheng University, Taiwan
Hsiu-Ju Wang, Chao Yang University of Technology, Taiwan
Yin-Hui Cheng, National Taichung University of Education, Taiwan
Shih-Chieh Chuang, National Chung Cheng University, Taiwan

11L Does Rejection Make You Feel Better? The Influential Role of Choice Type in Post-Purchase Regret
Chao-Feng Lee, National Chung Cheng University, Taiwan
Hsiu-Ju Wang, Chao Yang University of Technology, Taiwan
Yin-Hui Cheng, National Taichung University of Education, Taiwan
Shih-Chieh Chuang, National Chung Cheng University, Taiwan
19P The Effect of Busyness on Consumer Preference For Joint Consumption ................................. 981
Jaewoo Lee, Boston University, USA
Frederic F Brunel, Boston University, USA

6C Assessing Health-Being in Community: A Community-Based Participatory Evaluation of the Veggie Rx Program in a Northeastern Community .................................................. 981
Ada Leung, Pennsylvania State University, USA
Lisa Weaver, Pennsylvania State University, USA

18A Price Promotion: How the Presentation of Price Drop Affects Purchase Intention .................. 982
Mengmeng Liu, Chinese University of Hong Kong, China
Jessica Y. Y. Kwong, Chinese University of Hong Kong, China

10B Parents’ Debts, Children’s Obligation? The Effect of Similarity on Consumers’ Boycott of Parent and Subsidiary Corporation ................................................................. 982
Yung-Chien Lou, National Chengchi University, Taiwan
Wei-Chih Tseng, National Chengchi University, Taiwan

9L To Split or Not to Split? The Impact of the Breadth of Giving on Future Donations ...................... 982
Matilde Lucheschi, City University of London, UK
Oguz A. Acar, City University of London, UK
Jonathan Zev Berman, London Business School, UK

19B Online Shopping Cart Abandonment: A Consumer Mindset Perspective ................................ 983
Chrissy Martins, Iona College, USA
Dan Rubin, St. John’s University, USA
Diogo Hildebrand, Baruch College, USA
Veronika Ilyuk, Hofstra University, USA

Matthew Maxwell-Smith, Western University, Canada
Allison R. Johnson, Western University, Canada
June Cotte, Ivey Business School, Canada
Sharon Shavitt, University of Illinois at Urbana-Champaign, USA
Steven Shepherd, Oklahoma State University, USA

61 The Quantified Self: The Effects of Activity Tracking and Anthropomorphization on Consumer Health Motivation and Behavior ................................................................. 983
Martin Mende, Florida State University, USA
Maura Scott, Florida State University, USA
Gergana Y. Nenkov, Boston College, USA
Anders Gustafsson, Karlstad University, Sweden
Lane Peterson, Florida State University, USA

1L The Impact of ad Depth of Field Matching Product Categories on Product Evaluation .................. 983
Lu Meng, Renmin University of China, China

2019 ACR Presidential Address

The Value of Wrong
Darren Dahl, University of British Columbia, Canada

My address today will be inspired by two distinct stories. The first centers on the battle between two competing iconic American brands: Mars and Hershey. Chronicled in the book “The Emperors of Chocolate,” the rise of these two brands—over 100 years ago—was driven by their two leaders: Milton Hershey and Forrest Mars. Milton Hershey was a leader akin to Willy Wonka, an eccentric and benevolent man who built a town in Pennsylvania—named Hershey—where he located his chocolate factory. He also sought to foster community by building parks, a library and an orphanage, among other amenities. In contrast, Forrest Mars began his career working for his father, but soon left the company to work for Hershey’s. After gaining experience working for the competition, he returned to Mars where he succeeded his father as president of the company. He was a strict leader, operating the company with a firm set of rules—a black book of protocols if you will. Forrest was renowned for maintaining his privacy; in fact, there are very few historical images of him on record. The company remains privately held to this day.

Hershey was the early market leader in chocolate in America, and the company was built around one specific chocolate bar brand—the Hershey Bar. One fascinating thing about this brand was the early business model that established it. Namely, the price point was fixed at 5 cents, and was held static at this level for decades. Of course this meant that the size of the bar varied as the price of cocoa futures rose and fell. Over time, the bar became progressively smaller, and this presented an opportunity for Mars. In the early 1950’s, Mars made a distinct strategic move and came to market with much bigger bars (e.g., Mars, Snickers, etc.) priced at 10 cents. The market reacted positively to this change, and for the first time in history Mars was the market leader in confectionary in North America. How did Hershey react to this strategic move? As one might guess, they pursued points of parity and increased both the price of the Hershey bar (to 10 cents), and the size of the bar. Unfortunately this was the wrong move; the market reacted even more negatively, and additional market share was lost. Indeed, the Hershey 5 cent bar had become an iconic brand in the American lexicon and any change to the concept of the 5 cent bar was seen as a betrayal. It wasn’t until the 1970’s when a movie producer came to Mars (the market leader) to see if the company would like to have its candy product placed in a feature film that the marketplace shifted once again. You see, in this instance Mars declined the opportunity, reasoning that consumers would not appreciate their candy being linked to a movie about aliens. When Mars declined, Hershey was approached next and they jumped on the opportunity, featuring their recently developed Reese’s Pieces (born of their acquisition of the candy company Reese’s in the 1960’s) in the movie. Of course both the alien film E.T. and the launch of this new candy were huge successes, and the marketplace saw another shift back to Hershey as market leader. In this instance, Mars miscalculated and missed an opportunity that validated a new promotion approach in the marketplace. The competition between these two companies has gone back and forth over the years, with both brands capitalizing on the mistakes and errors of the other.

The second story, perhaps somewhat bitter rather than sweet, revolves around the development of a tropical storm in the central Atlantic in August 2019 that became Hurricane Dorian. Dorian peaked as a category 5 hurricane with 185 mph winds, and on September 1st it became the biggest disaster in Bahamian history, leaving 3.4 billion dollars in damage and 70,000 people homeless in its wake. Dorian eventually dissipated two weeks later over Greenland. Important to this story, President Donald Trump tweeted on September 1st that this hurricane was likely to hit a number of U.S. states including Alabama. The National Weather Service responded to this tweet by clarifying that Alabama was actually unlikely to be hit by the storm. Doubling down on his tweeted statement, in a news conference on September 4th President Trump presented a doctored map that showed the range of the hurricane including the state of Alabama. Indeed, the map showed an extension of the storm bubble drawn with a black sharpie. The inability of President Trump to admit that he was wrong in this instance became known as #sharpiegate.

Contrast for a moment these two instances of “being wrong”. Why is it so hard to be wrong? First off, it feels way better to be right than to be wrong. There is no question our survival as a species depends on us being right more often than not. At a more macro level, being wrong comes at a cost, often a lost opportunity—as evidenced in the Hershey and Mars story. At a micro level, individually, being wrong and making errors reveals social, intellectual, and/or moral failings—somewhat ironic in the case of the President Trump story shared above. Why are these attributions made? Massimo Piattelli-Palmarini, an Italian cognitive psychologist, stated that errors are made due to “Inattention, distraction, lack of interest, poor preparation, genuine stupidity, timidity, braggadocio, emotional imbalance, ideological, racial, social or chauvinistic prejudices, as well as aggressive or prevaricatory instincts.” Given this, it is no surprise that people work hard to avoid being wrong! And we try to mitigate negative attributions when we are shown to be wrong (e.g., we like to say, “I was wrong, but…”).

Augmenting this, people delight in finding others in the wrong (e.g., told you so, gotcha moments, etc.). This is not something new; throughout history the social cost of being wrong has been significant. No story better illustrates this than that of the explorer John Ross. In 1818, John Ross, an explorer with thirty years of sailing experience, was hired by the British Admiralty to attempt to find the Northwest Passage—a goal that had transfixed Europe for centuries. With two ships, and a plan to leverage the earlier exploration efforts of William Baffin, John Ross sought to explore the Smith, Jones, and Lancaster sounds in search of a viable pathway. It was during his final exploration of Lancaster Bay that he identified the Croker mountains through the fog. In his words: “I distinctly saw the land, round the bottom of the bay forming a chain of mountains connected with those that extended along the north and the south sides. This land appeared to be at the distance of 8 leagues…The mountains, which occupied the center, in a north and south direction, were named Croker’s Mountains, after the Secretary to the Admiralty.”

Upon returning to England and in his report to the Admiralty, his second in command—William Perry—refuted his account of the Croker mountains, stating that no such land form existed. Indeed, on a return voyage William Perry verified that John Ross had been wrong, the mountains truly did not exist. In fact, John Ross had been the victim of a superior mirage, often found in the Arctic, whereby temperature inversion and light refraction can cause visual illusions and distance misperceptions. Unfortunately, John Ross’ mistake be-
came a social spectacle and he was vilified in the press of the day. His reputation was significantly damaged, despite the other topographic, scientific, and trade contributions he had achieved on this voyage.

Given all this as storyline, where is the upside in being wrong? People have an abhorrence and fear of being wrong...and rightly so? What's the positive? One possible answer lies in a line penned by philosopher and theologian Augustine over 1600 years ago - "Fallor ergo sum" – I err, therefore I am. Indeed, I would argue that being wrong is what makes us human, and consequently there is fundamental value in being comfortable with the errors that one makes and encounters throughout one's life. In Kathryn Schulz's book "Being Wrong", the characterization of value in being wrong centers on three specific areas:

First, being wrong enables you to build compassion and empathy for others. For me, this was made clear by an experience that occurred in my first year as an associate dean at UBC. Our undergraduate students had independently organized what we call a "fresh" event here in Canada – a welcoming event at the start of the year for new students. This particular event involved the typical activities for this age group – games, cheering, drinking, etc. The students had rented school buses for transportation to the venue, and on a few of these buses fresh chants broke out. Unfortunately, a number of these chants were extremely inappropriate (i.e., misogynistic, racist) and social media quickly picked up the story. Within hours, the Dean's office at the business school was facing direct questions from mainstream media regarding the incident. As a result the students involved in the fresh event were punished, and it fell to me to work with some of the students to counsel them moving forward. Social media had been especially hard on some of these students, with people in the business community calling for them to be expelled from school, blacklisted from job opportunities in the community, and deserving of other harsh repercussions that seemed over the top to me. This was especially tough for some of the female student leadership who had not been directly involved, but had been nevertheless held responsible. I will always remember the maturity of one of these young women, who at 19 years old was able to see some value in the experience as a lesson in compassion for others. Through tears she indicated that she hoped others would not have to experience the anxiety, shame, and guilt that she had felt over the missteps that had been made. An element of wrongness had given this young woman the empathy to feel for others who might be – rightly or wrongly – so harshly accused.

Second, being wrong facilitates the learning and development so critical to maturity. This second outcome of error is quite personal to me as it represents a big turning point in my own life. You see, my background is in accounting; it was the focus of my first degree and the context of my initial working experience in the business world. However, I quickly realized this path was not for me, and before returning to academia to complete my PhD in marketing I took a gap year in the hospitality industry. A managerial position at Tony Roma's (a place for ribs) was just the ticket I needed to earn some money and recharge my batteries before facing a new academic challenge. Upon completion of my year at Tony Roma's, I thought it best to ask the general manager for a reference letter. After all, in my mind I had been a stellar manager and had thereby added real value to the organization. To my surprise, my boss, Dave Murphy, sat me down and indicated that he wouldn't be writing me a letter of recommendation because I had really been unimpressive over the duration of my employment at the restaurant. Dave related that although I was clearly intellectually sharp and scholastically accomplished, I was condescending to my colleagues and customers and lacked the work ethic that was key to success in the industry. Stunned, I realized how wrong my self-evaluation was, and that I had completely miscalibrated my job performance. Even worse, there was nothing I could do at that time to rectify the situation; my error was fundamental and irreparable. This sharply painful learning experience has been the keystone in how I now look at being a responsible employee in any context. Being wrong in this instance was the best development experience I could have received.

Finally, being wrong is both fundamental and critical to science and discovery. An early story from Richard Feynman, the Nobel prize winning physicist, shows why this is true. He recounts that as a young child he and his father spent time together observing nature; his father would consequently challenge him to make predictions based on these observations. In one instance, Feynman relates that they both noticed that when birds landed after flight they would pick at their feathers. Asked to hypothesize why, young Feynman opined that the birds did this to realign the feathers that had been disrupted during flight. However, after additional observation Feynman noted that birds picked at their feathers long after finishing their flight, and thus realized he was completely wrong in his prediction. He came to understand that birds picked at their feathers to eliminate small insects that had found a home therein. Feynman notes that the experience of being wrong in such inquiry at an early age paved the way for his approach to science and discovery.

Indeed, many would contend that science in general depends on being wrong. Seminal work centered on the philosophy of science points to the strong need for falsification. Karl Popper famously asserted: "In so far as a scientific statement speaks of reality, it must be falsifiable; and in so far as it is not falsifiable, it does not speak about reality (1959, p. 316)". Thomas Kuhn's notion of paradigm articulates that normal science exists until revolution is achieved due to things that cannot be accommodated – the inability of a theory to facilitate wrongness underlies the true structure of scientific revolutions. Pessimistic Meta-Induction from the history of science (Lauden 1981) takes an extreme view, arguing that all scientific theories will be found to be wrong over time (despite the perspective of the realist view). The notion of a flat earth, a geocentric universe, existence of ether, and cold fusion have all been falsified despite being central tenets of science at one point in history. Even in anatomy, it was believed for hundreds of years that women had one fewer ribs than men (until they actually counted perhaps).

Herein lies a question I have for our field: I wonder if we are thinking about replication as a way to enhance or evaluate the integrity of our findings. As an editor of the Journal of Consumer Research (i.e., in the 70’s and 80’s) we were much more open about admitting error. Authors would identify that their hypotheses were wrong. This seems to have been largely lost; this openness to “being wrong” is gone.

As an editor of the journal, I often saw members of the review team of a submitted manuscript demand the replication of effects from a previous paper if the submitted work was to move forward in the review process. The notion
that previous published work could not “be wrong” was surprising to me.

• Now that I am past-editor (residing in the Editor Old Folks home) I have been surprised that younger authors indicate to me that they feel anxiety over being wrong in their work, even when their approach seems appropriate and replication has been achieved. It seems that they are worried over potential outcomes like John Ross, and that they might be socially destroyed by those looking for wrong.

One could question - as a field - is there a danger of navel gazing here? I don’t have an answer, just observations. I believe many, if not all of us have produced research that will eventually be shown to be wrong - context, population/samples, the effects of time - these are examples of factors that contribute to the potential to be wrong in our field. How comfortable are we with admitting the possibility that our work might be wrong? Interestingly, academics like Richard Muller and Richard Spitz have admitted they were wrong years after taking extreme positions in the articulation of their original theses. Most recently, it was noted that Peter Radcliffe’s winning of the Nobel Prize in 2019 was an identification that the journal Nature was wrong in rejecting his work 27 years earlier. What is my hope? That as consumer behavior scientists, it is important to remember we are generative not archival”, and being wrong is, in my opinion, fundamental to that viewpoint.

To finish, I would like to pull back a bit from academic musings and relate a final story. This past spring I was traveling down to Mexico City for some work on behalf of my school. Like many do, I made a gambit at the airport for an upgrade, but was informed that business class was full. The desk agent was excited to tell me that she could put me in the seat right behind business class – uh, that’s still economy? The plane was indeed full and I was surprised at the heterogeneity of the passengers – people from everywhere. Next to me was a young fellow who I ascertained was likely from Korea. Most surprising was that he was wearing what appeared to me to be a fake security guard uniform – maybe that’s what was fashionable with the kids today? The flight itself was uneventful, and upon landing and reaching the gate I jumped up to get my carry-on (I was in an aisle seat of course). I was surprised however when someone “rushed the aisle”, knocking me right back into the seats and onto the lap of the fake Korean security guard. I popped back onto my feet and squared up, ready to get hostile with whomever had knocked me down. To my surprise it was a young female traveler who was fashionably dressed. My confrontational airs quickly deflated and I resigned myself to some muttering about queuing theory and such. As we walked towards immigration and the reception hall, I noted a number of young women, walking quickly, bumping me to the side, and generally working to get ahead at any cost. I found myself entering the “road rage” mental zone as cuts in the line continued to occur. Eventually, I had to ask – what is happening? A fellow traveler leaned over and uttered one word – K-pop. Then it hit me; I was on the plane with NCT 127 and all of the drama with other travelers was simply saesang doing what they do. I felt embarrassed for how completely wrong I had been on my attributions towards motivation. As I walked into the reception hall and saw thousands of screaming fans waiting for their pop heroes I had to chuckle at my comeuppance. I realized I get fired up waaaaay too easily, and would benefit from reminding myself that I might be wrong, accepting it more quickly when I find that I am, and working harder to learn from it.

Does our society have a healthy tolerance for being wrong? Where does it sit for you - in your life, your compassion for others, your learning, and the way you approach science? I would leave you with these questions – I believe there is value in being wrong – do you?

REFERENCES

Popper, Karl R. (1959), The Logic of Scientific Discovery, Hutchinson.
Good evening everyone! I am certainly happy to be here and feel very fortunate to have this experience.

As the Association for Consumer Research asserts in their statement of purpose, ACR’s mission is to advance consumer research and facilitate the exchange of scholarly information among three constituencies—academia, industry, and governments worldwide. Certainly, ACR has been and continues to be successful in pursuit of that mission. Part of the work of ACR is the recognition of deserving fellow consumer research colleagues like Linda Price and Chris Janiszewski.

First and foremost, I would like to express my sincere gratitude to ACR for being named an ACR Fellow. Obviously, I am very pleased to have received such a wonderful recognition, albeit one that certainly was not expected.

Please note that I have been retired from the University of South Carolina for a number of years. I now am spending more time playing golf, reading, and watching my grandchildren grow. As such, I am really not in a position to comment on the state of consumer research as is often done in Fellow recognition ceremonies. Therefore, my remarks will be brief and focus, first, on thanking those who have helped so much throughout my career and, second, offering a few insights from some of the lessons I have learned during my career as a professor at the University of South Carolina and as a consumer researcher like most of you attending this conference. Third, I would like to discuss an area I believe consumer researchers can help with.

To begin, I must acknowledge the inspiration that I received from my University of South Carolina colleagues, for whom I have the deepest respect and who motivated me to be better than I would have ever been otherwise. Much credit goes to my faculty colleagues and doctoral students. In particular, I would like to recognize and thank retired dear USC friends Jim Hilton, Terry Shimp, Subhash Sharma, and Jess Teel, as well as former South Carolina colleagues Rebecca Walker Recez, Randy Rose and Joe Urbany, now at Ohio State, Tennessee and Notre Dame, respectively.

I have also had the opportunity to work closely with a number of doctoral students and to chair a number of dissertations. Some of those students are here today. While I will not take your time with providing a complete list, I would be remiss if I did not mention by name the following individuals, now all productive faculty members at their own institutions: Donnie Lichtenstein, Rick Netemeyer, Ken Manning, Pam Ellen, Kelly Hewitt, David Hardesty, Kelly Haws, Robin Soster, Stefanie Robinson, and Meredith David. Again, I learned so much from these former students and very much enjoyed and benefitted from the chance to work with each of these wonderful individuals. Obviously, I am proud of their own accomplishments and their promise for the future.

**A FEW LESSONS LEARNED**

To begin, many factors influence one’s career—family, friends, our own universities and departments, and simple chance. In my case, my wife Patti and the USC Marketing Departmental have provided continual support throughout my career.

For young faculty and doctoral students, my experiences and observations of successful scholars suggest the following:

1. Consider carefully the competitiveness of the areas in which to focus your research, as well as your own strengths and weaknesses. For example, while analytics is now a promising area, one should consider their own analytical abilities before concentrating their research there.
2. Generally, be programmatic and focus upon a select few areas of research concentration. But, unexpected opportunities for excellent publications may arise in areas other than one’s apparent interests. These opportunities should be taken advantage of, if feasible. For example, during a seminar one semester, and after reading in the seminar several articles on market orientation, I commented that a meta-analysis on the market orientation-performance relationship might be an idea worth pursuing. Ahmet Kirca, now at Michigan State, and Satish Jayachandran, a colleague from USC, with some modest help from me, pursued that idea—now one of my most cited articles (Kirca et al. 2005), but certainly far-afield from my areas of interest in consumer research.
3. It seems to me that one troublesome phenomenon in the review process that should be addressed by journal editors and associate editors is the notion of “moving targets” in terms of reviewer reactions to submitted revised manuscripts. It seems from my experience and listening to author colleagues that too frequently reviewer reactions to first revisions include sometimes new demands from reviewers of the manuscripts that might well have been raised in the first round of reviews.
4. Take time to regularly reflect on your classes and teaching. Many research-active faculty are excellent teachers. And, the impact that we as faculty can have on undergraduate and graduate students is profound. In addition, try to match your teaching with your research interests. The synergy that results can positively impact one’s performance.
5. Working with doctoral students is one of our most enjoyable activities and an important responsibility as well. On occasion, you encounter instances in which inexperienced faculty expect too much from beginning doctoral students. Joint faculty-student effort involves more than just providing to the student a set of articles and then asking the students to read and then return with a publishable idea. From my experience and from observing colleagues who have worked effectively with doctoral students, personal concern for the student in all aspects of their life greatly facilitates the student’s growth and their development as researchers and eventually faculty colleagues. Be patient with your students; all of us develop at varying rates.
6. Lastly, I would like to offer one broad topical suggestion for consumer researchers from my own recent experiences. Moreover, the following ideas are consistent (1) with ACR’s mission statement regarding “industry” as one of our threefold emphases and (2) with transformative consumer research areas of interest (e.g., Mick 2012).

Briefly, and since my retirement, I have had the opportunity to offer some assistance to our local outreach organization, WE CARE, which supports the needy in our community Northwest of Columbia, SC. My volunteer work largely involves food assistance efforts and...
obtaining damaged packaged goods (e.g., paper products, cleaning supplies, diapers, etc.) given by Wal-Mart to a United Way facility in Spartanburg, SC. The facility is part of a reverse logistics distribution process, whereby returned, damaged and unsold merchandise are processed. Many of these items are given to charities, such as WE CARE.

From my prior involvement with Stephanie Robinson’s (NCS) dissertation, it is my understanding that the altruism literature has investigated extensively the motivations underlying volunteerism (e.g., Mowen and Sujan 2005). And likewise, charitable giving and donations have been investigated often by consumer researchers. But so often, the focus is on the volunteer and/or the giver, and less so on those in need. Relatedly, the coverage of poverty in general, and foodbanks and food pantries in particular, in JCR and JCP has been limited.

One in seven children regularly face hunger in the US, leaving them without access to critical sources of energy they need to learn and grow. A similar percentage of adults face the same set of challenges. Foodbanks and food pantries, all non-profit organizations, are: (1) staffed by volunteers, (2) salvage and store food that would normally go to waste, and (3) then distribute their collections to the needy. Some large foodbanks service other frontline agencies. Importantly, and thanks to the involvement of volunteers, data suggests that 98% of all donations, including both food and financial donations, go to those in need.

Overall then, it seems apparent, and as Eileen Fischer (2013) and others have argued, that consumer researchers, who are well-equipped through their methodological and theoretical training, might well address in greater depth the causes of financial deprivation, as well as activities that might assist consumers in need. In some sense, the activities of many outreach organizations, such as the thousands of food banks and food pantries within the US, reflect the efforts of “consumers helping consumers”. Overall, and as Rich Lutz and others have stated in arguments for research relevance (e.g., Lutz 2018), these efforts would enhance our focus on pragmatic utility (Alba 2011).

In conclusion, as consumer researchers, we are equipped with more resources than ever before to do meaningful work and to interact with colleagues studying a litany of fascinating topics from different vantage points. One of my great joys in this stage of my life is being able to utilize some of my time and energy to engage in work that will help fortify the basis from which our field and society will grow: young people seeking to learn. We, as academics, have a tremendous responsibility to pass along our knowledge, experiences, and insights to the next generation of scholars and consumer researchers. Having the opportunity to help shape the futures of students, both within and outside the realm of academia, has provided me with a profound sense of satisfaction. This recognition today is a much appreciated honor, and our presence here today provides me with confidence that the future of our field is engaged, thoughtful, and in capable hands.

Thank you again!

REFERENCES
Empirical consumer research is informed by, in part, psychology. Research in psychology has been characterized by three competing paradigms. Relativism, assumes that an investigation of lived experience (e.g., perception, meaning, feeling) depends on a personal meaning system, hence, is always subjective (Baghramian 2004, 2010). Relativists reject the assumption of universal and permanent truths and, instead, focusing on how experiences inform the behavior of individuals, social groups, societies, and cultures (Arnould and Thompson 2005). Behaviorism attempts to explain behavior using events in the environment, as opposed to cognitive representations and/or transformations of these events (Baum 2017). Behaviorists tend to study the environmental factors that influence the rate, intensity, and persistence of a behavior over time. Cognitivism assumes that environmental inputs can be represented in a mental code (i.e., information), that this code can be subjected to a series of mental transformations (i.e., processes), and that these mental processes are responsible for all behavior (Gardner 1987).

Relativism, behaviorism, and cognitivism inform present day research on consumer behavior. In my fellow address, I will focus on behaviorism. Behaviorism was the favored paradigm in psychological research from the 1920 through the 1950’s. Although it has lost favor over the past 60 years, the principles of behaviorism have always been present in psychological and consumer research. In some cases, behaviorist principles have guided research on a particular topic (e.g., mimicry, habit formation, evaluative conditioning, sensory marketing, retail atmospherics). In other cases, behaviorist principles have blended with cognitivist principles to inform an approach to studying a topic (e.g., error-correction models, connectionist models, dynamic sequential choice) or theories about behavior (e.g., associative learning theory, embodied cognition, functionalist perspective on emotions). I will discuss the principles of the behaviorist paradigm, how they have manifest in prior research, and how they are likely to shape consumer research in the present and the future.

BEHAVIORISM

Over the first half of the 20th century, behaviorism became a major paradigm for psychological inquiry. The start of the behaviorist movement is credited to John Watson (1913), who observed that much of the psychological research at the time investigated mental concepts that were not directly observable. Watson rejected introspection as a valid, scientific method. Instead, Watson advocated the study of observable behavior. He argued that psychologists should “never use the terms consciousness, mental states, mind, content, introspectively verifiable, imagery and the like.” Although these concepts were well-accepted sources of human behavior, they were not verifiable sources of behavior. This put psychology at an epistemological disadvantage to the hard sciences (e.g., chemistry, physics). Watson’s strategy for legitimizing psychological research was to limit inquiries to questions that could be investigated via the direct observation of behavior, a position that was consistent with logical positivism. If a behavior could be observed, quantified, and altered, then it was worthy of scientific inquiry.

The behaviorist’s approach to understanding human behavior shifted scientific emphasis in four ways. First, there was the emphasis on observable behavior. The goal was to understand how the environment shaped behavior, how behavior was reinforced, the means by which behavior could be made more intense, frequent, or persistent, as well as the means by which behavior could be dampened or extinguished. Second, there was an emphasis on the environment. Researchers wanted to know how stimuli came to cause behavior (i.e., became conditioned stimuli), what made a stimulus an effective elicitor of predictor (e.g., stimulus salience, latent inhibition), how stimuli competed to become future causes of changes in behavioral, and what moderated the influence of stimuli on responses. Third, there was an emphasis on combining small behaviors to produce complex ones, a motivation that could be traced to the desire to differentiate psychology from biology (Crowther-Heyck 1999). The goal was to understand molar, as opposed to molecular, behaviors as well as how sequences of these behaviors could be developed and/or modified. Fourth, there was a deemphasis on using mental events as explanatory variables. This is not to say that behaviorists denied the existence of thought. Instead, thought was a response that could, but often did not, serve as a stimulus in a stimulus-response-outcome triad (Skinner 1957).

Present day behaviorists vary in the extent they emphasize different parts of the stimulus → black box → behavior model. Although most non-behaviorist define behaviorism and a strict stimulus-response paradigm, only psychological behaviorists assume that stimuli and/or environments are the only source of behavior (i.e., there is no need to refer to an internal process). Analytical behaviorists accept that there may be mental processes that intervene between the stimulus and the response, but prefer to use non-mental terminology (e.g., drive, habit strength, drive reduction, homeostasis). For example, Hull (1943) allowed that there could be intervening states that did not relate to the environment (e.g., an identical environment could produce competing responses), but that these states were related to drives. Purposive behaviorists emphasize observable behavior, but are more relaxed about the definition of a stimulus environment (i.e., what are acceptable stimuli) and the possibility of an intervening process. For example, Tolman (1932) argued that one could infer “internal acts, states, mechanisms, processes, structures, capacities, and properties” as causes of behavior, but that one would have to set up critical tests to differentiate between the mental events (e.g., goals, mental maps, adaptation).

The Advantages of Behaviorism

There are six major strengths of the behaviorist paradigm. First, the paradigm does not need to assume an organism has an innate structure that allows it to learn (e.g., Piaget’s innate schemas). There is behavior, there is feedback, and there are learned contingencies. Second, the behaviorist paradigm is dynamic. The focus is on how behavior changes over time (Miller and Frick 1949). Classical conditioning, operant conditioning, shaping, and habit formation

---

1 It is important to note that I refer to research paradigms, as opposed to philosophies of science: e.g., relativism (Kuhn 1962), social constructivism (Latour and Woolgar 1978), falsificationism (Popper 1968), and epistemological anarchism (Feyerabend 1975).
are models that allow one to predict changes in the rate, intensity, and persistence of behavior. Third, the paradigm focuses on effect sizes. The goal is to understand how to facilitate positive behavior and extinguish negative behavior. The larger the change in behavior, the more relevant the intervention. Fourth, there is an emphasis on ecological validity. Environments are responsible for behavior. Changes in an environment result in changes in an effect size. Hence, understanding the characteristics of an environment that create an effect provides insight into the replicability of the effect. Fifth, the behaviorist paradigm is not constrained by theory. Most behaviorists do not consider mediating cognitive processes, thus, their research questions are not constrained by a specific theoretical perspective. One might say behaviorists are more inductive, though many would disagree because there is often is an emphasis on identifying descriptive models that predict changes in behavior over time (e.g., Janiszewski and van Osselaer 2000). Finally, the paradigm encourages a focus on substantive issues. If one is interested in behavior, then it is beneficial to study consequential behavior.

The Advantages of Cognitive Science

First proposed by Allen Newell and Herbert Simon, and later championed by George A. Miller, the premise was that the mind could be represented (reality is in the mind), but argue that this subjectivity is represented (reality is in the mind), but argue that this subjective representation is processed according to a set of learned rules (processing code).2 Further, one could assume that processing code (i.e., the software of the mind) was agnostic to the information (i.e., data) subjected to the processing he code, thus, the problem of relativism is avoided (Crowther–Heyck 1999; Shannon 1948a, 1948b).2 Second, it established an agenda that invited large participation. The goal was to identify pieces of processing code and/or understand the execution of a sequence of processing code. Cognitivism provided an opportunity to learn about attention, perception, comprehension, memory, inference, reasoning, etc. Third, it reduced the barriers to doing research. Behaviorism required a lab, staff, and the maintenance of animals. Cognitivism required paper, pencils, and access to human subjects. Conceptual and methodological skills could be taught. Thus, the computer metaphor supported efficient and inexpensive methods of data gathering.

The second factor facilitating the cognitive revolution was the work of Noam Chomsky. Chomsky investigated language acquisition and production, and area that behaviorist had a difficult time explaining (Skinner 1957). Chomsky (1959) observed that the rapid acquisition of language, as exemplified by three-to-five year-old children, could not have been learned via reinforcement. In fact, children at this age could easily create novel sentences (i.e., generative grammar). Chomsky further noted that ability to generate, improvise, and adapt language depended on innate abilities linked to modular systems in the brain. Thus, his view departed from a strict computer metaphor in that he assumed the computer code (software) was not agnostic to the type of information being processed by the code (i.e., language processing and production depended on codes that were, in part, specific to the type of information). Finally, Chomsky noted that people remember the gist of what was said, not the specific content of an utterance, suggesting that heard language was transformed into an abstract representation.

Seventy years of research have generated tens of thousands of articles that rely on the cognitivist paradigm. Common to many of the early articles is an emphasis on understanding processes in the mind. Yet, as time has passed, there has also been more investigation of the information that reemerges from these cognitive processes. Beliefs, attitudes, evaluations, judgments, choices, reasons, hedonic experience, etc. have become important topics in psychological and consumer research.

The Disadvantages of Cognitivism

There are five major weaknesses of the cognitivist paradigm. First, the paradigm is consistent with human’s beliefs about free will. Many cognitivists assume that people can control the mental processes that are responsible for behavior – executive intervention is possible. Hence, it is worthwhile to study the cognitions that are assumed to be responsible for behavior. Second, the cognitivist paradigm is adaptive. To the extent people behave in ways that are inconsistent with stated intentions, there are paradigmatic adjustments (e.g., automatic behavior, implicit learning, heuristics, non-consciously directed behavior, distraction) that can explain why a more reasoned process did not direct behavior. Third, the cognitivist paradigm provides theoretical generalizability. To the extent constructs represent the causes and effects of behavior, theories can be informative about anticipated outcomes in a variety of contexts.

The Disadvantages of Cognitivism

There are five major weaknesses of the cognitivist paradigm. First, the paradigm encourages domain-isolationism (Maxwell

---

2 This relativist principle was subsequently dropped, as it interfered with the assumption that everyone in a specific experimental condition experienced equivalent content.
Theories and methodologies are developed with process-specific questions in mind, so that there is little overlap with related domains and little resemblance to natural behavior. Second, the paradigm is regressive (Maxwell 2019). Any serial model of stimulus representation (i.e., perception), cognitive processing (e.g., information processes), and intention (e.g., behavior selection) can be challenged because the process account is not sufficiently detailed. As process accounts become more detailed, contributions become more incremental. Third, experienced mental events (e.g., thoughts) are often uncorrelated with behavior (Wegner 2002; Wilson 2002), lag behavior (Libet 1985), misrepresent the actual sources of behavior (Nisbett and Wilson 1977), or provide no insight into the sequence of processes that are responsible for behavior – assuming such a sequence exists (Hommel 2013; van Gaal, de Lange, and Cohen 2012). Thus, the paradigm uses a methodological approach that emphasizes unreliable data (a form of process introspection). Interestingly, this implies that cognitivism has not solved the relativism trap that behaviorist tried to avoid when they rejected relativism. Fourth, it ignores a fundamental tenant of all animal behavior – that organisms are always in transition. The unit of observation should be the change in behavior over time, not the state of behavior at one time (i.e., longitudinal studies should be the norm, not the exception). Finally, cognitivism cannot address the mind-body contingency. The mind is not independent of the body any more than information is independent of information processes (Barsalou 2008; Wilson and Golonka 2013).

A PARADIGM SHIFT: BECOGNITIVISM IN CONSUMER RESEARCH

“Paradigms do not die. As new ones are born, the old ones can survive and even prosper” (Duranti 2003). Duranti’s observation does not describe the initial fate of behaviorism in cognitive and social psychology, but it may describe the persistence of behaviorist principles. That is, while there has not been a resurgence of behaviorist methodology, some of the remnants of behaviorism can be seen in present-day research programs. First, research on mimicry places a strong emphasis on the replication of the behavior that is being observed in the environment (Chartrand and Lakin 2013). Second, the functionalist perspective on emotions posits that emotions are a motivational response to the specific environmental circumstances that initiated the emotion (i.e., the source of the emotion matters) (Keltner and Gross 1999; Witherington and Crichton 2007). Third, the literature on sensory marketing investigates a vast array of environmental and experiential factors that directly influence behavior (Peck and Childers 2008). Fourth, investigations into on-line WOM have placed a larger emphasis on the characteristics of the communications and the consequential responses of the receivers (Berger 2014). Fifth, research on nudges has identified a number of interventions that are valued for their effectiveness, as opposed to their theoretical insight (Thaler and Sunstein 2008). Finally, emerging research using big data places more emphasis on predicting consequential consumer behavior, and less emphasis on the reasons for relationships between predictors and predicted events (Hofacker, Malthouse, and Sultan 2016).

I would like to argue that the popularity of these domains of research represents a shift back toward three behaviorist principles. Across all research domains, there has been an increased emphasis on actionable interventions, an increased emphasis on consequential behavior, and decreased emphasis on theoretical advancement through process explanations. At the same time, there has been a reluctance to abandon cognitive process theory, so that research has shifted toward documenting processes that account for relationships between actionable interventions and consequential behaviors. That is, it is sufficient to offer a process account (i.e., mediating process) that is a conceptual replication of existing theory, as opposed to an extension of a theory, as long as the account provides insight into the potential generalizability of the effects in a natural environment. I call this new paradigm beCognitivism and define it as studying the influence of the environment on behavior using cognitivist principles. That is, we seek to understand the influence of actionable interventions on consequential behaviors as explained by existing theory (see MacInnis et al. forthcoming for an alternative perspective on this trend).

The emergence of the beCognitivism in consumer research can be traced to five events. First, researchers were made aware of a problem with existing research. As discussed in Rich Lutz’s 2018 fellows address, there have been calls for more relevance in consumer research dating back to 1991. Year after year, everyone thought they were doing relevant research only to learn, upon reflection, that everything they published was irrelevant (or so our thought leaders claimed). Sarcasm aside, researchers were producing incremental work, though this was likely a characteristic of the cognitivist paradigm (see above) and those who embraced it (e.g., reviewers). Second, researchers where made aware that there was an alternative paradigm. In 2005, David Mick (ACR Presidential Address) championed the Transformative Consumer Research movement. Mick created a forum for doing research that emphasized actionable interventions and meaningful consequences. Over time, a critical mass of people embraced key behaviorist principles, knowingly or not, that supported research contributions intended to make a difference in society. Third, there were nudges toward the paradigm. In John Deighton’s (2007) editorial on “walking the fences” between theoretical and applied research, a plea was made for research that was more actionable. Deighton observed that experimental consumer researchers were at a resource disadvantage relative to psychologists, hence, could not excel at knowledge generation in the theory development domain. He argued that we should place more emphasis on developing non-generalizable insights at the intersection of theory and practice. Deighton encouraged authors of theory papers to add a single study that spoke to an actionable interventions and/or meaningful consequences. He also added a special Journal of Consumer Research issue (2008, edited by David Mick) on consumer welfare. In a later editorial (Deighton et al. 2010), he called for research that was “heavy on effects and light on theory” and, subsequently, championed these types of papers. All of these were effective nudges. Fourth, the emphasis on theoretical insights had to be relaxed among gate-keepers. Although Deighton and co-editors had pushed for this change, reviewers and ERB members were predictably slow to embrace the change. That is, papers that used an actionable intervention and measured a consequential behavior were at a disadvantage to traditional, cognitivist papers because the beCognitivist papers naturally emphasized external validity over internal validity and/or theory advancement. This problem was addressed in fall, 2015 when the Dhal, Fisher, Johar, Morwitz team of JCR editors began to consider, and eventually publish, papers that had actionable interventions and consequential outcomes. These theory application papers demonstrated how consumer research could make a difference in society and that theoretical advances were not the only route to knowledge creation in consumer research. Accordingly, an effort was made to develop, and enforce, evaluation criteria that emphasized societal impact and theoretical insight, without requiring theoretical advancement. Finally, incentive systems were aligned with the new paradigm. The Campbell, Kirmani, Imman, Price JCR editorial team has used editorial feedback to encourage papers that
are consistent with behavioral principles. I note that their editorial emphasis is aligned with the *Journal of Marketing* and the *Journal of Marketing Research*, which are also encouraging beCognitiveist research. As an aside, my perception is that *Journal of Consumer Psychology* remains open to both cognitivist and beCognitiveist research.

The renewed emphasis on the key behavioral principles of (1) actionable interventions, (2) consequential behavior, and (3) theory application (as opposed to theory development) is shifting our research focus from theory building to the generation of actionable knowledge. This has implications for how we will evaluate future knowledge contributions. To illustrate why this is the case, let’s compare and contrast the foci of cognitivist and beCognitiveist consumer research in the present day.

1. **An emphasis on theory development (cognitivism) vs. an emphasis on behavioral impact (beCognitiveism).** Cognitivist researchers try to advance existing theory. The most common implementation in consumer research is to adopt a theory from cognitive or social psychology, add a previously undocumented mediating process, identify a moderator that determines when the new process versus a previously established process is more likely to have an impact, and show the differential influence of these two mediating process on downstream behaviors (i.e., constructs). BeCognitiveist researchers try to demonstrate how to make a meaningful difference in a managerial, social, or consumer domain. The most common implementation in consumer research is to find an important behavior (e.g., eating, health behavior, on-line behavior, recycling, donation behavior, addictive behavior, financial decision making, medical decision making) and isolate interventions that can influence this behavior. Secondary data, field studies, and consequential lab behaviors can be used to bolster claims that the research demonstrates how to impact an important consumer behavior.

2. **An emphasis on constructs (cognitivism) vs. an emphasis on interventions (beCognitiveism).** Cognitivist researchers manipulate constructs, or measure constructs, so findings can be generalized to out-of-domain contexts. To illustrate, consider the effort invested in guaranteeing construct validity. Authors are careful about defining constructs, and using established manipulations and measures, so that claims about theory are internally valid. BeCognitiveist researchers identify interventions that result in meaningful changes in consequential behavior. When the goal is to change a behavior, it is often advantageous to find an intervention that is strong and actionable, even if the intervention represents multiple constructs. To the extent the goal is to alter behavior, not develop theory, this emphasis is appropriate. I would further argue that the more representative the intervention, and consequential the behavior, the less important it is that the intervention be directly tied to any one construct.

3. **An emphasis on internal validity (cognitivism) vs. an emphasis on generalizability (beCognitiveism).** Cognitivist researchers strive to identify relationships between constructs. Internal validity is critical to any claimed relationship between the constructs. This necessitates a careful construction of procedures. It also requires that alternative explanations be addressed. BeCognitiveist researchers strive to identify relationships between actionable interventions and consequential behaviors. An implicit assumption of this paradigm is that all meaningful behaviors are multiply-determined. Thus, the objective is not to rule in an explanation and rule out all other competing explanations. Instead, the goal is to document an explanation that may provide predictive insight.

4. **An emphasis on mediation (cognitivism) vs. an emphasis on moderation (beCognitiveism).** Cognitivist researchers strive to understand why. They focus on theory development and hold the belief that a more developed theory will provide more predictive insights into more contexts. BeCognitiveist researchers acknowledge that it is important to understand why, but note that it is often more important to understand when and where. They focus on theory application and hold the belief that there are contextual factors that facilitate or inhibit relationships between interventions and behaviors. An actionable intervention is a useful tool and the goal is to understand when and where the tool will be useful.

5. **An emphasis on directional effects (cognitivism) vs. effect size (beCognitiveism).** Cognitivist researchers strive to understand directional relationships between constructs: “an increase in construct A will lead to an increase in construct B.” In this context, concerns about replicability relate to whether or not the relationship between the constructs holds across repeated tests of the hypothesis. BeCognitiveist researchers strive to identify successful interventions. In this context, concerns about replicability relate to whether or not an intervention will produce the same effect size across repeated tests of the hypothesis (see Nelson, Simmons, and Simonsohn (2018) for discussion). These differences in philosophy are related to a differential preference for understanding construct relationships (i.e., theory development) versus identifying variable relationships (i.e., theory application).

My discussion of the differences between cognitivism and beCognitiveism are broad, coarse, and extreme. There are few researchers that claim to support all of the beCognitiveist positions I have stated, especially given that the large majority of empirical consumer behavior researchers were trained in the cognitivist tradition. Yet, my observations do not come from my imagination. In the past three years, I have seen subsets of these beCognitiveist views expressed in reviews, AE reports, and Editor decision letters. Further, I am seeing them with increasing frequency.

Independent of the review process, there are pieces of evidence that are consistent with the idea that we are in a paradigm shift toward beCognitiveist research. First, consider the shift in topics studied by information processing researchers over the past 10 years. In the 2008 issues of the *Journal of Consumer Research*, researchers largely investigated mental events: beliefs, evaluations, intentions, judgments, experiences, scenario-based choices, etc. In fact, only three papers (out of the 58 non-Consumer Culture Theory papers), approximately 5%, measured a consequential behavior (e.g., a consequential choice, food consumption). In contrast, in the 2018 issues of the *Journal of Consumer Research*, nine papers included a study with a consequential choice and 12 additional papers had a study with a consequential behavior (e.g., tipping in a restaurant, cheating, donation amount, menu choices in a restaurant, gambling, food consumption, WOM – tweeting, product purchasing). This represented 34% of the 61 non-CCT papers. This reflects a broader shift toward the investigation of consequential behaviors (e.g., physical consumption, financial decision making, social influence, socially responsible behaviors). This shift will continue as more emphasis is placed on resource usage, product disposal and reuse, interactions with technology, online search and viewing behavior, and online communications (e.g., Facebook, Twitter, Snapchat). Calls for more socially consequential work (e.g., MacInnis et al. forthcoming) will further accelerate this paradigm shift.
THE CONSEQUENCES OF A PARADIGM SHIFT

It is difficult to predict the end-state of a paradigm shift. Paradigm shifts are social phenomena that move at various speeds, owing to environmental nudges, but will move none-the-less. Yet, if the paradigm shift has just begun, then it is likely that we will experience considerably more disruption before a steady state is reached. If this is the case, I can offer predictions about where the field of consumer research will be 10 years from now. I offer these predictions not because I advocate these outcomes – my advocacy, or lack thereof, is irrelevant. Instead, I want to encourage mentors and students to make their own assessment about the expected state of consumer research five and ten years from now. I encourage everyone to have a conversation, and sharing their conclusions with their colleagues, so we are in agreement (or disagreement) about the future of the field. With that goal in mind, I offer some observations that can start the conversation.

1. **Consumer research will become more inductive.** To the extent beCognitivism encourages nudge-like studies, a researcher can deduce an effective nudge from theory or induce an effective nudge from observing a single case in the environment. I expect that observation and inductive reasoning will become an important source of ideas on how to create actionable interventions. These approaches will prove fruitful because they will take advantage of the fact that multi-causal interventions create larger influences on consequential behavior. The only advantage a cognitivist will have is the ability to combine theories to deduce an intervention that could integrate the effects of multiple causal constructs. Of course, this approach to science would be inconsistent with training of the cognitivist. That being said, case studies will provide a lower risk approach to understanding how to develop successful interventions.

2. **Secondary data, quasi-experiments, and field studies will lead contributions, whereas lab studies will support an explanation.** An increasing emphasis on actionable interventions and consequential behaviors will force researchers into research environments where both behaviorist principles can be concurrently achieved. Consequential behaviors can be observed in a lab, or with an online sample, but actionable interventions are difficult to implement in a lab unless the domain of research is ubiquitous (e.g., technology usage). I anticipate that researchers will have to document the importance of a research question, and the potential impact of their intervention, prior to offering an insightful explanation. The importance of the explanation for the relationship between the intervention and the consequential behavior will be negatively correlated with the generalizability of the effect across applied domains. Thus, as we begin to focus on applying theory to important managerial, social, and lifestyle issues, it will become less important to document that a theory was instrumental to the observation. Lab studies have the potential to lose relevance in these types of knowledge contributions.

3. **Consumer research will become more egalitarian.** In the same way the cognitive revolution reduced barriers to entry (into the knowledge creation industry) relative to behaviorism, a shift to the beCognitivist paradigm will reduce barriers to entry relative to the cognitivist (see van Osselaer and Lim 2019 for an alternative perspective on barriers to entry). The two biggest barriers to entry in the cognitivist paradigm are the conceptual and the methodological skills associated with theory development. Traditionally, these skills were taught in top Ph.D. programs, through coursework and intensive mentoring. Students who did not have access to this training were blocked from making contributions to top-tier journals. In contrast, beCognitivism requires that a person be able to observe the environment and understand basic influences on human behavior. The necessary skills for a beCognitivist researcher will consist of some combination of data scraping skills, data compilation skills, big data analysis skills, and project management skills (needed to run one-factor quasi-experiments and field studies) as well as an understanding of many of the methods that have supported CCT research over the past 40 years. The emphasis will be more on intervention implementation and testing, and less on theoretical development and advancement.

4. **Ph.D. students will be recruited for a different skill set.** Top Ph.D. programs have often recruited students because of their skills in conceptual thought, deductive reasoning, experimental design, and multivariate data analysis. A movement toward beCognitivist research will place more emphasis on applicants’ substantive interests, industry research experience, business networks, project management skills, and salesmanship (Maclain et al. forthcoming). People with these characteristics will be better able to accumulate and configure the resources needed to investigate actionable interventions at a local or national level. People with these skill sets will move our field closer to addressing social issues like poverty, inequality, climate change, etc. To the extent these are the goals shared by a majority of consumer researchers, the time for our educational interventions is now.

SUMMARY

Consumer research is in the midst of a paradigm shift. Ten years ago, over 90% of published, experimental consumer behavior research concerned theory development. In 2019, my impression is that approximately half of published, experimental consumer research will advance theory, with the remainder having a more applied focus. Ten years from now, there is a strong possibility that theory development papers will be absent from the consumer research journals. If this is the intent of the journal policy boards, then it would be useful to openly state this policy shift. It will help students and junior faculty make decisions about how to allocate their resources. If this is not the intent of policy boards, then it would be useful to set guidelines for how theory development and theory application research should be uniquely valued. It is unfair to reject a theorist’s contribution because the research used literature-based, and verified, manipulations and measures of constructs (i.e., did not have actionable interventions and/or consequential outcomes). It is also unfair to reject an applied researcher’s contribution because the research failed to make a theoretical advance, even though it documents, conceptualizes, or addresses an important consumer, societal, or global problem. In the end, a paradigm shift should introduce a new approach to making a knowledge contribution, but it should not extinguish the old way of making a contribution. The history of our field shows there are many approaches to making a knowledge contribution.

The Fellowship and The Quest
Linda L. Price, University of Oregon, USA

I’m deeply humbled and honored to be named an ACR Fellow. Those of you who were at the ACR luncheon table with me last year know I was astonished to learn I had been named. Many of you out there in the audience may still be astonished that I was named! Let me clarify that I could not possibly be a bigger fan of the research I’ve done—each and every research journey I undertake seems destined to change the world and make it a better place (at least in my mind). And, I haven’t given up on any of them (published or unpublished)—as my mother used to say “Hope springs eternal.” I still think it’s only a matter of time before everyone realizes how interesting and important they are. And it’s a really good thing I feel this way, because I spend literally years on each and every one of them.

Being named a Fellow, however, highlights for me, it’s never a fellow, it’s always a fellowship. Each and every one of my research projects has a story, and the story is quite similar—there’s a fellowship and a quest. As I say this, at least some of you are likely to nod your heads in agreement that your research stories are like that too. So, I’m not saying something new or profound, but I want to focus on both parts of this narrative, the fellowship and the quest, because I think they often get backgrounded in how we describe the research process—sometimes to our students, and sometimes to ourselves.

I’m going to begin by describing what I mean by a fellowship and a quest. Then I’m going to conclude by describing how they come together to shape the research process and outcomes. I hope a way, because I spend literally years on each and every one of them.

Being named a Fellow, however, highlights for me, it’s never a fellow, it’s always a fellowship. Each and every one of my research projects has a story, and the story is quite similar—there’s a fellowship and a quest. As I say this, at least some of you are likely to nod your heads in agreement that your research stories are like that too. So, I’m not saying something new or profound, but I want to focus on both parts of this narrative, the fellowship and the quest, because I think they often get backgrounded in how we describe the research process—sometimes to our students, and sometimes to ourselves.

I’m going to begin by describing what I mean by a fellowship and a quest. Then I’m going to conclude by describing how they come together to shape the research process and outcomes. I hope a modest take away is that when you are recruiting and working with PhD students, choosing and doing your research, reporting and talking about why and how you did what you did, you might reflect a bit more on the wonderful gift of these two things.

THE FELLOWSHIP

My brothers, I see in your eyes the same fear that would take the heart of me. A day may come when the courage of men fails, when we forsake our friends and break all bonds of fellowship, but it is not this day…This day we fight!! J.R.R. Tolkien

It’s not surprising that I would focus at least part of my talk on fellowship since much of my research career has emphasized not the individual actor, but the collective; not my identity, but ours; not me, but us and our relationships with each other as citizens in a global world (Epp and Price 2008; Epp and Price 2010; Epp, Schau and Price 2014; Strizhakova, Coulter and Price 2008; Thomas, Price and Schau 2013). When I’m studying consumers’ possessions, I’m most interested in how possessions are assembled into and affect people’s relationships with each other (Epp and Price 2010; Curasi, Price and Arnold 2004). When I’m studying markets, I’m most interested in how they are shaped and shape people’s interactions (Price and Arnold 1999; Arnold and Price 1993; Feick and Price 1987). When I study brands, I’m interested in how consumers’ most important loyalties (which almost never include brands) affects their brand choices and use (Price 2015). When I look at service touch-points in the customer journey, I imagine that customer to be a family on a collective journey, with complex identity goals (Epp and Price 2011; Epp and Price 2018; Thomas, Epp and Price 2019).

Naturally, as I reflect back on my research career (something that I suspect inevitably happens when given this honor) I see all the amazing, fruitful, and happenstance fellowships that comprise those research journeys. Also, it’s perhaps not surprising that on the 50th anniversary of the Association of Consumer Research, I am drawn to thinking about fellowship since this association has been a vibrant partner in each and every one of my research journeys. As I look across this room I see many fellow travelers.

There’s been a lot of work on research collaborations, what they are, how they impact productivity and how to create, find or enhance successful ones (c.f. Bammer 2008; Lee and Bozeman 2005; Katz and Martin 1997). Research collaborations are one important way of thinking about fellow travelers. I won’t pretend to have a comprehensive grasp on that literature, but will say that, in general, research collaborations are increasing and increasingly important for addressing major social, environmental and technical problems, and successful ones are still not that common. Many, if not most research universities, including my own, have major initiatives in place to encourage successful research collaborations particularly in quests of solutions to vexing problems.

The more encompassing term of fellowship has a simple definition. For example, the Cambridge Dictionary defines fellowship as “people with the same purpose, experience, or interest, or a formal organization of these people,” noting “Fellowship is also a friendly feeling that exists between people who have a shared interest or do something as a group.” Nevertheless, in our daily lives we know that fellowship is difficult, complicated, ephemeral and dynamic. Sometimes we gather together in pursuit of a shared goal and it feels in our bones like a fellowship, and sometimes it does not. Like so many other prized emotions and experiences, we have trouble providing the formula for a fellowship, and yet “we know it when we see it.”

As I was trying to articulate in words, what exactly makes a good fellowship, I ran across an interview with Tom Reilly program director for Ted Fellows, who described what he looks for in a Ted Fellow (Eng 2014):

I’ll take a stab at it: intellectual, energetic, social and emotional fluency. Pick at least two or three. Add a porous-membrane attitude to collaboration, genuine optimism and a love for playing idea-jazz alone and in bands.

At least in research fellowships these qualities seem like a pretty good start on a recipe, and I bet all of us feel that ACR is a fellowship that enables us to “play idea-jazz in bands.” But we also know that fellowship means we take turns taking out the garbage, make sure we proof-read everything until our brains are numb, and make sure it’s not just talk, even if the talk sounds brilliant. Daniel Kahneman has spoken compellingly about research fellowships, observing of his long-time and fruitful collaboration with Amos Tversky:

One consequence of this mode of work was that all our ideas were jointly owned. Our interactions were so frequent and so intense that there was never much point in distinguishing between the discussions that primed an idea, the act of uttering it, and the subsequent elaboration of it (Kahneman 2003; 724).
He goes on to write, “Amos and I shared the wonder of together owning a goose that could lay golden eggs—a joint mind that was better than our separate minds.” Most important he writes of the excitement, the fun, the laughter, even positing that because of Amos he became funny and “the result was that we could spend hours of solid work in continuous mirth,” (723). As someone who has experienced this kind of collaborative work with many of my fellow travelers it is magical, “solid work in continuous mirth,” could not be a better description. My own lovely fellowships add in lots of spices, spontaneity and adventure—and very often a beach, river or mountain. Nevertheless, just like any other collective, to be effective, research fellowships have to harness heterogeneity, create and navigate flexible connectedness, and regularly support their collective goals, despite many competing priorities (Price and Epp 2015; Thomas, Epp and Price 2019; Thomas, Price and Schau 2013).

I want to emphasize that I define the fellowship of a particular research journey as including not only that inner circle of research collaborators whose names often go on the related publications, but also the many others who inform, support and direct the quest. Many of you in this room have served this role providing directions, offering fellowship, support and traveling along side. These unacknowledged fellow travelers can have a central role in how a journey unfolds. To understand how and why we have to talk about the quest.

THE QUEST

“Say it, reader. Say the word ‘quest’ out loud. It is an extraordinary word, isn’t it? So small and yet so full of wonder, so full of hope.”

—Kate DiCamillo

The quest is the most important part of research. Cambridge dictionary defines a quest as “a long search for something that is diffcult to find.” When you go on a quest, there’s a sense that it will require risk, skill, stamina and vigor; you can’t predict where it will take you or what lies ahead; there will be obstacles; and when you complete the quest you will have found something important that will benefit not just you, but others as well. Such long and arduous journeys almost always involve fellow travelers. They are initiated in a variety of ways and for a variety of reasons. We have wonderful examples in our field of these kinds of arduous journeys: long and arduous quest to improve consumers’ health and wellbeing (c.f., Mick et al 2012; Pechmann and Knight 2002; Zhao and Pechmann 2007); a long and arduous quest to improve the lives of cancer patients and their families as they interact with service systems (c.f., Berry, Dalwadi and Jacobson 2016; Danaher et al 2017); long and arduous quests to improve individuals’ financial journeys (c.f., Fernandes, Lynch, and Netemeyer 2014; Lynch 2011; Lynch et al 2009); and a life-long quest to do “action-oriented programs of research aimed at improving society and the lives of consumers” (c.f., Murray, Ozanne, Shapiro 1994, p. 559; Ozanne and Saatcioglu 2008; Ozanne et al 2017). Of course, there are lots of other examples in this room right now of these types of arduous quests. These examples feel like “holy grail” quests, but quests come in all shapes and sizes.

Over years of serving on University P&T and University Graduate Councils I have had a chance to review a lot of research that involves fruit flies. I thought, “What would it be like to spend your life studying fruit flies?” Of course, these researchers weren’t studying fruit flies, they were on grand quests to understand genetics, recover habitats, save species, and cure diseases. At the heart of their research are burning questions that give this tiny organism a giant role in scientific research (c.f., Cohen 1995; Prokop 2016). At least five Nobel prizes have come from studying these irritating little critters that inevitably end up in your wine glass on a summer night. These flies are studied so fruitfully exactly because they are a teeny, tiny convenient example of so many important things.

I’m currently reading a memoir by Hope Jahren, a paleobiologist, entitled Lab Girl. I should confess when I say “currently reading,” what I mean is I pick at it, highlight particular passages throughout, put it under my pillow and hope to actually read all the way through it soon. The author has a great Prologue, which I promise will suck you into the whole book. She is on a long and arduous quest to save trees and forests. She asks us to care that more than one trillion leaves are being ripped from their source of nourishment every single day. She asks us to care about the deaths of those leaves. Then, Professor Jahren asks us to focus our gaze on just one leaf, reflecting “People don’t know how to make a leaf, but they know how to destroy one.” She encourages us to ask a question about our leaf. The most important part comes next! When we do that, when we begin to ask a burning question of that leaf that caught our gaze, we are a scientist. It may help to know math, or physics or chemistry (or in our field psychology, sociology, anthropology, economics, statistics). However, the essential feature of a good scientist is a burning question. In fairness, Professor Jahren says “what comes first is a question, and you’re already there,” (4). She doesn’t explicitly say it has to be a burning question, but I think if you are going to undertake a long and arduous quest then it needs to be a burning question. Let me briefly answer two important things you might be asking, “What is a burning question?” and “How do I find one?” Of course, I realize that some of you are simply asking “When will this be over?”

What Is a Burning Question?

A burning question can be one that many people share, something that if we knew the answer would make a big difference to a lot of people in their beliefs, behaviors, and outcomes. It could be what keeps a lot of people awake at night. Those “holy grail” quests I described earlier seem like this. Jerry Zaltman, a significant mentor for me and many others in this room, always encourages us to ask, “how many people will change what they are doing by how much, if you answer this research question?” Specifically, “An interesting idea is one that, if it were ‘true’, would require a large number of people to undertake a substantial change in their beliefs or behaviors (Zaltman, LeMasters, Heffring 1982).

However, burning questions can also be something that if you knew the answer would make a big difference in your beliefs, behaviors, and outcomes. That is, a burning question can be something firmly rooted in your own life, something that keeps you awake at night. Most of my burning questions are quite personal, rooted in my own experiences. For example, triggered by the birth of my son I went on a multi-year journey with fellow travelers to understand family identity and consumption. How do families create and maintain heirlooms (Price, Arnould, and Curasi 2000; Curasi, Price and Arnould 2004)? What is family stuff (Price 2013)? How do objects and technologies enter our households and disrupt our identity and practices (Epp and Price 2010)? How are multiple identity goals (sometimes painfully) navigated on a family vacation (Epp and Price 2011)? How does technology mediate family practices (Epp et al 2014)? Each of these was triggered by a specific observation in my own life. Since I’m not so different from a lot of other people, it turns out my burning questions are generally shared by many fellow travelers as well. Fellowships are made up of the people who share your quest. You’ll have a chance to hear some of my fellow travelers (Matt Godfrey, Kivalina Grove and Nate Warren) present some of our recent burning questions during this ACR conference (Godfrey and Price 2019; Grove and Price 2019; Warren and Price 2019). And I’ll be back next year and the years after with more of them.
How to Find a Burning Question

Significantly, burning questions rarely come from observing thousands of data points—although a burning question can easily send us on a quest to observe or collect sheaves of data. Rather, burning questions often come from the careful observation of just one thing—a person, an event, an experience, an object, a story—a single leaf, or a chance encounter with a total stranger (Gladwell 2019). They are often formulated around an N of 1, that then draw our gaze to many other instances and the importance of that observation. They are our interpretation of that one thing, from our particular perspective. They can make us feel as if we have opened a door and walked through it to an entirely different possible world, one that doesn’t behave as we expected and leaves us confused, disturbed, unsettled—believing there is something very important about this observation that we just don’t get. In a fabulous chapter on designing a program of research, social-psychologist Susan Fiske describes an early burning question. Moving to Boston for college she describes:

I was struck by an absence that took me awhile to place. Although there was the right amount of fluffy white stuff, the people were far too white. The lack of ethnic variety in the Boston I encountered—the result of heavy de facto segregation—seemed odd to me. Probably primed by my mother’s interest in communities, I couldn’t figure out why people would want to live that way. Probably primed by my father’s orientation to research, I realized there must be empirical answers, (Fiske, 2004, 71).

Virtually all my research journeys look exactly like this. They began with a single observation that seems very confusing and at odds with how I think the world works, and I believe there are empirical answers. Quite often the specific observation never appears in the published work, but nonetheless plays a central role in the research journey. Because these doors into possible worlds are not written into the research process, we may neglect how vitally important they are (Bruner 2009). We may neglect to tell our students that it is finding these doors, opening them, and walking through that is the most important part of all. These doors are portals that take us between now and then, between what and what if, they transfigure us (Price and Price 2019). As architect Simon Unwin marks,

where the power of the wall is to deny (to keep things apart), that of the doorway is to permit (to allow passage). And permission usually has more dimensions of possibility—risk as well as rewards—than denial.”

(Unwin 2009, p. 3).

Karl Weick writes about these possible worlds: “When people imagine reality, they start with some tangible clue and then discover or invent a world in which that clue is meaningful,” (1731), but he warns us that to walk through these doors into a possible world requires simultaneous believing and doubting. “Faith involves a full intensity of commitment to action but doubt fine tunes that faith by differentiating things known from things not known,” (Weick, 2006, 1730).

HOW THE FELLOWSHIP AND THE QUEST TOGETHER SHAPE THE RESEARCH PROCESS

I want to conclude my comments by talking about how the fellowship and the quest come together to shape the research process. To set the stage for that conclusion, I want you to recall the wonderful Dr. Seuss story of “Horton Hears a Who.” In case you need something to trigger that memory, I brought the book. Much of what I have already suggested is eloquently unfolded in this quintessential ethnography. In this story, you just have to insert for Horton the elephant, the collective of the fellowship, the fellowship of people who believe that there’s a possible world living on a speck of dust and if you listen very carefully you will uncover this possible world. The informant of this world will play a role too—if you start to listen they will rally and yell. They’ll tell you their story—because “A person’s a person. No matter how small.” And, there will be surprises and empirical demands—you’ll ask that mayor to call out all hands and make sure you can prove that Who’s in Who Ville are really there, you’ll make sure you get everyone out and everyone’s there. And the end of the story, as we like to recall, is the Who’s in Who Ville were saved by “the smallest of all.” Ever after the big kangaroo said she was planning to help save them and the young kangaroo in her pouch said...me too.

I have been extraordinarily lucky because I have found many fellow travelers to pursue possible worlds on a speck of dust. I mention only a few here. Larry Feick was willing to go on a multi-year search to find out if there were more people like Mark Alpert (that wonderful but bewildering person we later called a Market Maven) (Feick and Price 1987). Eric Arnould, with a single phone call from a near stranger was happy to undertake a multi-year study of how a bunch of bad things adds up to consumer delight (Arnould and Price 1993), how service providers manage these kinds of extended service encounters (Price, Arnould and Tierney 1993), and how commercial friendships emerge and their consequences (Price and Arnould 1999). One burning question after another emerged from a single day rafting trip years before I ever met Eric that left me bewildered about why my companions thought that was “so much fun” and “we should do it again.” Amber Epp, Tandy Thomas, Hope Schau and I are figuratively fellow travelers forever in our quests to understand our families and our tribes—what holds us together, what pulls us apart? It is an engaging and dynamic quest that changes with each new twist and turn in our respective family journeys. For example, Tandy and Amber, both parents of young children, recently published an engaging multi-year study of why and how carefully envisioned new parenting practices are not what actually happens, aptly titled, “Best Laid Plans,” (Thomas and Epp, 2019). I suspect our collective journey to understand our collectives will never end. Robin Coulter has now been on so many perilous and arduous quests with me that she deserves sainthood. Our most recent quest to understand how a fresh start mindset shapes consumer consequences began when I was about to go on sabbatical in 2013, desperate for a fresh start. On a hike through Sabino Canyon in Tucson Arizona, we began our quest and have gathered fellow travelers. We are still questing, and still inviting fellow travelers (but see, Price et al 2018).

My fellow travelers have brought an equal bounty of belief and doubt. They have had my back, and never let me get away with anything. They have been as invested in the quest as I am. They too love the question much more than any particular answer. They believe that what we find can change their lives and others. They have a complement of skills and tools, but also solid empirical rules. As Dr. Seuss might coin, they have followed me out “to the three millionth flower, searching and searching hour after hour.” Through thick and thin they have made me better. All the storms they’ve helped me weather.

When I wish for you the greatest of things—and I do, I wish that you might have these two things—a fellowship and a quest.

David A. Schweidel, Emory University, USA
Beth L. Fossen, Indiana University, USA

SESSION OVERVIEW

From the excitement of iPhone launches to the uproar over Nike’s Colin Kaepernick campaign, emotions have a huge impact on attitudes and action. Indeed, decades of consumer behavior research has scrutinized emotion and its effects.

But to truly deepen wisdom in this area, research must move beyond the confines of the lab. How can researchers measure emotion in the field? And how can we better understand emotion’s impact in noisy real-world environments?

This session integrates four papers using diverse text analytic approaches to shed light on these questions. How do emotions evoked by online content shape reading? Can expressing positive emotion actually decrease others’ purchase intent? Does venting about an experience really hurt businesses? And which emotions expressed by politicians generate engagement? This session answers these and other questions as it deepens our understanding of the emotional consumer in the wild.

Examine 35,000 articles, Berger, Moe, and Schweidel examine how emotions shape reading. Using natural language processing they demonstrate that the effects are more complex than mere emotionality or valence alone. Instead, specific emotions have differing effects. Evoking anger and anxiety encourage further reading whereas sadness discourages it. Directly manipulating these emotions in an experiment underscores their causal impact and highlights the underlying role of uncertainty and arousal in driving these effects.

Analyzing over 100,000 Amazon reviews and three in-lab experiments, Rocklage and Fazio investigate whether positive emotion can backfire in online reviews. For product owners, positive emotion is consistently linked to higher star ratings. When expressed to others, however, this same positive emotion backfires and decreases purchase intent for utilitarian products. Readers mistrust emotional reviews given the product’s unemotional nature. Consequently, these reviews are also less likely spread because they often do not reach the product’s front page on Amazon.

Grewal, Stephen, and Bart use 1.67 million online hotel reviews and five experiments to investigate when consumers vent negative opinions and when these opinions are harmful versus harmless. They find that consumers express greater negativity the more recent their hotel stay, but that these proximally-written reviews tend to be discounted by readers. Readers see the reviewer as less rational and therefore give that review less weight.

Schweidel and Fossen analyze 30,000 Twitter posts from U.S. senators to examine the effect of emotional language on multiple metrics of online engagement. Anger in particular predicts greater impact: it results in more retweets and replies and also predicts increases in the number of new followers the senator attracts. This effect is particularly strong when predicting new followers in states with greater partisanship. Sadness, disgust, surprise, and trust also play important roles.

Taken together, these papers create new wisdom on the measurement and impact of emotion in the wild. In addition to researchers studying emotion, online reviews, and text analysis, this session should draw those studying word of mouth, attitudes, digital behavior, and consumer engagement. Moreover, the unique datasets and text analysis approaches used should help expand researchers’ repertoire of data sources and methodologies.

What Leads to Longer Reads? Psychological Drivers of Reading Online Content

EXTENDED ABSTRACT

More and more consumers read content online. They scan Wall Street Journal articles, and peruse blogs on tech and celebrity gossip. But sometimes people only read a sentence or two before navigating to something else and other times they read a full article. What makes one article more engaging than another? That is, what about certain articles encourage people to keep reading?

This paper investigates how content characteristics shape continued engagement. We combine an experiment with natural language processing of a unique dataset of over 825,000 reading sessions from nine major online publishers. This data allows us to examine, for a given person reading a given article, how textual features of a given paragraph (i.e., the words used) shape whether someone keeps reading.

We make two main predictions. The first, more intuitively, the easier text is to process, the more likely people will continue reading. We measure processing ease both through standard textual complexity measures (i.e., Flesch-Kincaid readability index and syntactic complexity) and word familiarity and concreteness. More familiar words should be easier to process and concrete things tend to be easier to visualize or imagine, which should make processing easier and encourage reading.

Second, we examine how emotions evoked affect reading. The most basic possibility is that emotionality, or sheer amount of emotion, impacts reading. A second possibility is that valence drives...
reading: positive things encourage reading and negative things discourage it, or vice-versa.

In contrast, we suggest a third possibility: different specific emotions (measured through NRC) will have different effects on reading based on their associated appraisal and action tendencies. Specifically, we suggest that effects will depend on how specific emotions shape uncertainty and arousal. Uncertainty involves not knowing or not being sure about something. While certain emotions (e.g., anger) tend to be characterized by certainty, others (e.g., anxiety or fear) tend to be characterized by uncertainty (Lerner and Keltner 2001). Uncertainty, in turn, increases attention and information search as people try to resolve predictions about what will happen next (Tiedens and Linton 2001). Taken to the context of reading, we suggest that emotions associated with uncertainty (e.g., anxiety and sadness) should encourage reading.

Beyond uncertainty, emotions are also characterized by differences in arousal. Arousal is a state of being physiologically alert and attentive. While some emotions (anger and anxiety) are characterized by high arousal, others (sadness) are characterized by low arousal. Emotionally arousing stimuli attract attention (see Mather, 2007 for a review). Taken to the content of reading, we suggest that emotions characterized by high arousal (e.g., anger and anxiety) should encourage people to continue reading.

We test these predictions in both the field and lab.

Field Data

We use natural language processing to analyze over 825,000 page read events from over 35,000 online articles. We worked with a major content intelligence company that tracks reader engagement for online publishers. For the last two weeks of October 2014, they provided a representative random sample of page-read events from nine popular online news sites (e.g., CNBC, ESPN, Wall Street Journal, and Jezebel).

Space constraints restrict full description the data, but for each page-read event we know how far down the article someone read and the text of the article before that. We include various controls (e.g., publisher, reading device, and article topics [using LDA for topic model controls]) to try to rule out selection concerns (e.g., certain types of people tend to read certain types of articles or at certain times). That said, one could still argue that some unobserved feature is driving engagement. To address this concern, we use article-level content features as a control. Thus, we examine whether controlling for all other observable aspects of an article, how the text of each paragraph relates to whether a user continues to read into the next paragraph. Even controlling for anxiety evoked by the rest of the article, for example, whether paragraphs that evoke more anxiety still increase reading.

Results

First, as predicted, emotion shapes reading, but the pattern is more complex than emotionality or valence alone. People are more likely to continue reading after paragraphs that evoke more anxiety or anger. They are less likely to continue reading, however, after paragraphs that evoke more sadness.

Further, consistent with our theorizing, people were more likely to continue reading after paragraphs that evoked greater arousal or used less certain or more tentative language.

Second, as predicted, a range of content features that should boost processing ease are linked to continued engagement. The variables that increase complexity (Flesch-Kincaid Grade Level and parse-tree height) hurt engagement and the variables that should increase processing ease (word familiarity and concreteness) increase engagement.

Experiment

To further test the role of emotion, and the underlying processes, we conducted an experiment.

We manipulated emotions exogenously through participants writing about a time they felt either angry, anxious, or sad, plus a neutral control condition. Then, as part of an ostensibly unrelated experiment, participants read part of a neutral article and reported their interest in reading more. Finally, to test the hypothesized underlying process, we measured how uncertain and physiological aroused participants felt.

If emotion impacts reading, as we suggest, then the emotion induced in the first task should spill over into the second. Even though everyone read the same article, the incidental emotion manipulation should impact reading. By keeping the actual article the same across conditions, and manipulating emotion incidentally, we ensure that any observed difference between conditions is driven by emotion rather than some other factor.

Results

Consistent with the field data, while anxiety and anger made people want to read more (compared to the control condition) sadness decreased their interest in reading more.

Further, a series of bias-corrected simultaneous mediation models demonstrate that specific emotions’ effects on reading were driven by arousal and uncertainty.

Taken together these findings make three main contributions. First, they shed light on psychological drivers of reading. Second, they help content creators design more engaging content. Third, they demonstrate how natural language processing can provide deeper insight into consumer behavior.

The Enhancing vs. Backfiring Effects of Emotionality in Consumer Reviews

EXTENDED ABSTRACT

A principal means by which consumers learn about products is through online reviews. Reflecting this importance, researchers have increasingly sought to understand what drives consumers to express their opinions online as well as the kind of content that is most impactful (King, Racherla, and Bush 2014). In this regard, a primary interest has been emotion. Literature reviews have put forth emotion as a predominate component of online content and word of mouth (Berger 2014; Hennig-Thurau et al. 2004). This research has emphasized that sharing emotional experiences is incredibly common (Rimé 2009) and that emotional content is more likely to become popular and spread (Berger and Milkman 2012). Moreover, consumers themselves turn to expressing positive emotion to persuade others to purchase a product (Rocklage, Rucker, and Nordgren 2018).

Thus, across researchers and consumers, there is a belief that greater positive emotional content should be more impactful. Is this the case? Past research on online reviews has focused on the effect of, for example, figurative language (Kronrod and Danziger 2013) or the level of energy a reviewer expresses (Yin, Bond, and Zhang 2017), but it has left emotionality – the extent to which an evaluation is based on feelings and emotional reactions – unexplored.

As background, reviewers and readers inherently view products from different perspectives (e.g., Packard and Berger 2017)“plainCitation”:(e.g., Packard and Berger 2017). Given that emotion is an integral part of the consumption experience, review-
ers naturally express emotionality when describing their experience with their product (Holbrook and Hirschman 1982). Readers, however, focus on the features of the product that are most important to them for their purchase decision. We show that when emotionality is a desired and expected facet of the product – e.g., hedonic products – positive emotionality has enhancing effects for both reviewers and readers. However, for products that are comparatively less emotion-evoking – e.g., utilitarian products – whereas this same level of positive emotionality continues to predict positive product judgments from reviewers, for readers it backfires and decreases their purchase intentions. Mistrust underlies this divergence: emotion expressed toward a utilitarian product evokes surprise and a sense that the review is odd, which leads to mistrust of the review. We examine these effects across five studies.

Study 1 used the Evaluative Lexicon (EL; Rocklage and Fazio 2015) to quantify the emotionality of 46,832 positive Amazon.com reviews written about approximately 500 hedonic and utilitarian products. Reviewers also provided a summary judgment via a final star rating. Regardless of product, the more positive emotionality reviewers expressed, the more positive their final judgment. Consumers visiting Amazon also judged these reviews for whether they were helpful or unhelpful (n_observations = 555,508). More emotional reviews were more helpful for hedonic products, but backfired for utilitarian. This held above the length of the review, when the review was written, and individual product fixed effects. Thus, emotionality predicted more positive evaluations from reviewers, but backfired for readers if the product did not naturally evoke emotion.

In Study 2a, we extended these results under controlled conditions. Participants (n = 200) identified a hedonic or utilitarian product they were positive toward. They then selected three positive EL adjectives that described their evaluation of that product and then gave a final judgment of that product (1: very negative; 5: very positive). As before, greater emotionality predicted more positive final judgments regardless of product type. These reviews were read by 242 participants who judged a random subset for 1) how helpful each was and then 2) their purchase intentions for that product. Using mixed modeling, emotionality was more impactful across both metrics for hedonic products, but backfired and decreased helpfulness and purchase intentions for utilitarian products. We conceptually replicated these results in Study 2b holding the product constant (hotels) and varying the hedonic versus utilitarian motivation for using that product.

In Study 3, we tested the theoretical proposition that mistrust underlies these effects such that 1) greater emotion toward utilitarian products 2) elicits surprise and a sense that the review is somewhat odd, which 3) leads consumers to mistrust the review, and thereby 4) leads readers to be less positive toward the product.

Participants (n = 196) read a product review that was either high or low in emotion and either hedonic or utilitarian (2x2 between-subjects). They then rated how surprising and odd the review was, their mistrust of the review, and whether they would purchase the product. As before, emotional reviews of hedonic products led to greater purchase intentions whereas emotionality backfired for utilitarian products. There was significant mediation: mismatching emotionality led to greater surprise and a sense the review was odd, which led to decreased trust in the review, which decreased the review’s impact.

In Study 4, we assessed a consequence of this effect: which reviews rose to the top for a given product and thus were more likely to spread and be read by others? We returned to Amazon and extracted all reviews (n = 128,938) for a random subset of the products in Study 1 (there were additional reviews given time had passed since Study 1). We recorded whether the review appeared on the product’s front page or not. More emotional reviews were more likely to rise to the top and be displayed on the product’s front page on Amazon for hedonic products, but less likely for utilitarian. Consequently, consumers are less likely to read emotional reviews of utilitarian products and they are therefore less likely to spread.

Whereas researchers and consumers alike tend to believe that greater positive emotionality is more impactful, we find that despite the unforced positivity of the reviewer, positive emotion can backfire when expressed to others. We demonstrate this has consequences for helpfulness, purchasing intentions, and the spread of content.

Managing Online Venting: The Impact of Temporal Distance on the Perception of Negative Online Reviews

EXTENDED ABSTRACT

Brands are concerned with negative online reviews as it is a popular source of information (Leffler 2018) that influence consumer product evaluations and sales (Chevalier and Mayzlin 2006). While research has shown that positive reviews are more widespread, they have less impact than negative reviews (Chevalier and Mayzlin 2006; Mizerski 1982). Although there is research that has examined the negativity bias (Baumeister et al. 2001), there is limited research on what reduces the negativity bias (Chen and Lurie 2013).

We propose that temporal contiguity, when combined with emotionality, may cause consumers to discount negative reviews. In the case of reviews that exhibit “venting” (i.e., the combination of a review expressing negative emotion while being temporally close; Dalebroux et al. 2008), we believe that the review may be causally attributed more to the reviewer, causing the review to be seen as less influential (Folkes 1988; Mizerski 1982). We believe this will occur as readers will get the impression that the reviewer wrote “in the heat of the moment” and thus, may not be rationally examining their negative experience. Therefore, we believe that when there appears to be more personal reasons for a negative review, as exhibited through venting, that it will be negative, rather than positive, information that is discounted. We test this prediction in real-world data and five experiments.

In Study 1, we analyzed real-world data from TripAdvisor covering 1,665,026 reviews from 2,393 hotels between 2010 and 2015. We tested the effect of valence (review rating) and temporal distance between review-writing and the experience (the ratio of past tense/present tense language; Pennebaker et al. 2007) on negative emotionality (the percentage of negative emotion words in the review; Pennebaker et al. 2007), controlling for other factors. We found the 2-way interaction to be significant (b=.002, p<.0001) wherein, we see on average more negative emotion when there’s less temporal distance between review writing and the stay and on average, we are more likely to see negative emotion when the stay and review occur close together. Essentially, we found that temporally close negative reviews were likely to exhibit negative emotionality, and thus, exhibit “venting.”

Next, we examined if “venting” influenced the perceived helpfulness of online reviews. We examined review rating, temporal distance, and negative emotionality on the count of how “helpful” a review was. We found a significant 3-way interaction (b=-.0002, p < 0.0001) along with significant 2-way interactions and main effects. The simple effects showed that the average helpfulness of a review associated with a low rating (e.g., 1 or 2 stars) and with moderate to strong negative emotionality (i.e., 50% or higher), will be lower when the review is written closer to the hotel stay. Conversely, when the temporal distance increases, the helpfulness count increases.
when there’s negative emotion. This finding represents our core prediction: Reviews that exhibit venting (i.e., temporally close negative expression) are more likely to be discounted (i.e., deemed “less helpful”), possibly because venting is attributed more to the reviewer rather than the situation. Alternatively, negative emotions that are temporally distant are not seen as venting, and thus are more likely to be viewed as “helpful” (replicating the negativity bias).

In Study 2a (n=406), participants were randomly assigned to a condition in a 2(valence: positive, negative) x 2(time of review: immediate, later) between-subjects design. Participants read the same hotel review that was framed as being positive (4 stars) or negative (2 stars). They were told the review was written either right after the experience or two weeks later. We found a significant interaction on purchase intentions (p=.004) where, for negative reviews, temporal distance mattered (p=.001), such that when a negative review was written close to an experience, participants had higher purchase intentions (vs. when time had passed). Temporal distance, did not matter for positive reviews (p=.282). Study 2b replicated this core finding in a 3(valence: positive, negative, neutral) x 2(time of review: immediate, later, no information) between-subjects design.

In Study 3a, participants (n=196) indicated their belief that they would consider a positively [negatively] rated restaurant when the review was written right after the experience [two weeks later]. Participants rated how rational the review appeared to be. We found significant interactions on purchase intentions (p=.040) and rationality (p=.028) where for negative reviews, reviews written soon after the experience were seen as less rational and had higher purchase intentions than negative reviews that were written with greater temporal distance. There were no differences among positive reviews (both p>.10). We found a significant index of moderated mediation through rationality (with timing of the review as the IV and valence as the moderator; Clp [-.004, .12]), wherein purchase intentions for negative reviews were significantly and negatively impacted by perceived rationality (Clp [-.12, -.01]). This effect was not significant for positive reviews (Clp [-.02, .03]). In Study 3b (n=187), looking only at negative reviews where temporal distance was manipulated through the review language (i.e., Today vs. Last week), we replicated the mediation results of Study 3a while ruling out a number of alternative explanations.

In Study 4 (n=325), we manipulated the causal attributes associated with the review. Using a 2(attention: reviewer, experience) x 2(time of review: immediate, later) between-subjects design with all negative reviews (same as in Study 3b), we found a significant interaction on purchase intentions (p=.078). Temporal distance mattered when the causal attribution of the review was on the experience (i.e., when there was no cues provided to make participants think the reviewer had personal motivations for the negative review outside experience; p=.004), such that when a negative review was written close to an experience, participants had higher purchase intentions (vs. when time had passed). Importantly, temporal distance no longer mattered when the review was causally attributed to the reviewer; in this case, both reviews, regardless of temporal distance, were discounted (p=.594).

Our results provide evidence that reviews that exhibit venting may be discounted, as negative information, when written in “the heat of the moment,” is seen as lacking rationality, leading to the information being seen as less diagnostic.

Engaging Your Audience on Social Media: An Application to Politics

EXTENDED ABSTRACT

Organizations are increasingly turning to social media to reach consumers. A growing body of research in marketing has focused on how characteristics of the message content affect consumers’ subsequent engagement with the post. While our knowledge of how content drives consumer engagement with social media, limited research has considered how characteristics of the audience may affect the extent to which they engage with an organization’s social media activity. In this research, we investigate message content and audience characteristics jointly affect consumers’ engagement with social media posts. As our empirical context, we collect nearly 30,000 Twitter posts from all U.S. senators during the first three months of the Trump administration. For each post, we observe the number of times that the post was retweeted and the number of replies the post generated. We also observe the change in followers on the days when senators’ post.

Our analysis reveals that the partisanship of the senators’ home states is informative of the extent to which their audience engages with them. We measure partisanship using Cook’s Partisan Voting Index (PVI), which calculates the amount by which a state’s vote share for a presidential candidate of a given party differs from the national average. Given the relatively close split between the Democratic and Republican parties, a PVI of 0 is indicative of a state in which there is a near even split between democratic and republican votes. In contrast, high magnitudes of PVI are indicative of a state that leans more heavily toward a single party. We contend that states with PVI values closer to 0 are comprised of multiple political ideologies and hence multiple audiences, whereas those states with high magnitudes of PVI values are more likely to be comprised of a single audience. Our analysis reveals that senators from states with high magnitudes of PVI amass more followers and have their messages retweeted more frequently than senators from home states with lower magnitudes of PVI.

In addition to this characteristic of the audience, we find that the emotional content of the Twitter posts from senators affects both the followers they amass and the degree to which their messages are shared by their followers. Using the NRC Emotion Lexicon, we identify the presence of eight emotions in Twitter posts: anger, anticipation, disgust, fear, joy, sadness, surprise and trust. We see that messages expressing anger, sadness and trust are more likely to be retweeted by followers. We also find that messages containing anger, disgust, sadness, surprise and trust generate more responses to the senators from consumers on Twitter. In contrast to the effects on replies and retweets, we do not observe a main effect of emotional content on senators’ changes in followers.

Beyond investigating the effect of emotions on consumers’ engagement with senators’ social media activity, we also consider the interaction between the partisanship of the senators’ home states and the emotional content of their messages. Consider a senator from a battleground state. This individual must appeal to both democratic and republican voters with his messages. In contrast, a senator from a state that leans more heavily toward one political party is primarily speaking to one party. We may therefore expect to observe differences in how consumers react to emotional content based on the degree of partisanship in the senator’s home state. To accommodate this, we interact both PVI and PVI² with the eight measures of emotions in our analyses. Our focus is primarily on the interactions between the emotions and the quadratic term PVI², as this measure reflects the ad-
ditional impact of emotional language on social media engagement for senators’ from more partisan states.

Our results suggest that social media messages expressing anger and disgust, two emotions that have been linked to higher arousal, are more effective at increasing followers in more partisan states. Social media messages containing sadness and trust generate fewer retweets and replies in these states. Overall, our analysis suggests that, even after accounting for the substantive content of the social media post and the presence of images, the use of emotional language affects the extent to which consumers engage with the posts. Moreover, the composition of the consumer base appears to moderate the impact of emotional language. We discuss the implications of our research for organizations seeking to build and engage their audience using social media.

**SESSION OVERVIEW**

Consumers face an overwhelming number of products at the marketplace. Essential challenges for most manufacturers are to make their products stand-out in a retail setting, effectively communicate the best information and increase the purchases of their products. This session aims to address these issues by exploring the roles of packaging. Across four papers, we demonstrate that packaging serves as a useful tool to help companies convey different product information and impact purchasing behaviors. Earlier research has found that packaging is a critical aspect of a product (Krishna, Cian, & Aydinoglu, 2017) and it can affect customers’ product experiences by changing perceptions of product size (Scott, Nowlis, Mandel, & Morales, 2008), shape (Folkes & Matta, 2004), and color (Ares & Deliza, 2010). The papers in this session further explore more nuanced and unexpected influences of package designs. The findings contribute to the sensory marketing literature, offer insights for marketers on how to best communicate product information via packaging, help consumers make better decisions to improve their lives and provide implications for policy makers on regulating packaging.

The first two papers in the session explore how visual elements of packages influence consumer perceptions of a product. This focus on changing product perceptions in a different modality provides an expansion of existing research on cross-modal effects (e.g., visual vs. auditory, Shen & Senpupta, 2013). In the first paper, Bi and Gunasti show that the amount of product information presented on the package positively impacts consumers’ perceptions of product weight and further affects willingness to pay for the products. This effect is driven by consumers’ lay theory that “information has actual weight and more information has more weight”. The second paper by Togawa et al. also tests the cross-modal effect, which demonstrates a visual–gustatory correspondence effect. This paper finds that food product image located at the bottom (vs. top) of the package façade enhances consumers’ perceptions of the flavor richness of the food, which reduces consumption quantity and subsequently leads consumers to choose healthy snacks. The other two papers in the session show that consumers’ expectations of a product’s healthiness can be altered by packaging elements such as font printed on the package-front and materials of packaging. The third paper by Deng and Flinger explores a typeface effect and finds that a natural font makes consumers perceive the product as healthier when the “healthiness” concept is made salient through an intrinsic cue or an extrinsic cue, or when consumers are sensitive to textual information. Finally, the fourth paper by Ye, Morrin and Kampfer finds a package type – healthfulness association. Specially, consumers infer a snack food packaged in a matte package as healthier than in a glossy package, which leads to a package material – purchasing motivation congruity effect. These findings provide important implications for consumers when consuming health-related products.

**The Unbearable Heaviness of Information: More Product Information = Higher Product Weight**

**EXTENDED ABSTRACT**

Consumer-packaged-goods explicitly provide weight information on the packaging. Yet, it is difficult for consumers to make sense of weight and perceptions of product heaviness can be very subjective. The current research investigates a strategy that marketers can use to manipulate perceptions of product heaviness: amount of product information presented to consumers. We further demonstrate how amount of information influences perceived heaviness of a product and its downstream consequences.

We proposed that the effect of information on weight is driven by people’s lay theory that “information has actual weight and more information has more weight”. People often use tangible metaphors to describe intangible concept such as information (for example: information is like water; Parker, 2000) and this metamorphosis of “information” into physical matter naturally introduces associations with physical properties such as weight. When people process a lot of information, they express the feeling as being “weighted down” as if too much information increases physical weight in one’s mind. Due to the abundance of similar information-weight associations in both eastern and western cultures, we propose a positive impact of information amount on perceived heaviness of a product. We further illustrate that when there is a positive (negative) association between weight and quality of a specific product, providing more product information enhances (hurts) quality inferences and WTP.

We conducted six studies to test these hypotheses. Studies 1a and 1b help establish the positive relationship between information amount and perceived heaviness. In study 1a, we manipulated the amount of information printed on a laptop adapter then asked the participants to infer the weight of the product (1= 0.5 lb., 100= 1.5 lbs.). We found that participants in the “more information” condition perceived the adapter as heavier than those in the “less information” condition. In study 1b, we manipulated whether the manufacturer wanted the adapter to be perceived as heavy or light then asked participants to decide how much information should be printed on the adapter. We found that when designing a heavy adapter, people put more information on the product compared to designing a light adapter.

In studies 2 and 3, we further test the association of product information and perceived heaviness. In study 2, we recruited English speakers and provided unreadable Chinese information in order to
manipulate information amount in a clean way. We found that participants in the “more information” condition perceived the pan as significantly heavier than those in the “less information” condition. In study 3, we adopted the dual-phase paradigm (Broniarczyk & Alba, 1994) for manipulating two opposing correlational beliefs about information and heaviness. We found that participants in the “more information = heavy-weight” condition were significantly more likely to identify a Kindle with 32 e-books (vs. 2 e-books) as the heavier product compared to those in the “more information = light-weight” condition. Importantly, while there was no difference between the control condition (no belief manipulation) and “more information = heavy-weight” condition, participants in the control condition were still more likely to identify the 32-ebook kindle as heavier compared to the “more information = light-weight” condition.

Study 4 aimed to rule out an alternative explanation of space occupied by information. Using a 2 (information: more/32 e-books vs. less/2 e-books) × 2 (space: empty vs. full) between-subjects design, we manipulated the space occupied by the information by either spreading those e-books over the full screen (full condition) or just occupying the corner of screen (empty condition). While there was no interaction of information and space on perceived heaviness, we observed significant main effects of space usage and information amount. Participants perceived the kindle displaying 32 e-books on the screen as significantly heavier than the kindle displaying 2 e-books.

Study 5 aimed to rule out an alternative explanation of location of information. In a single factor (information: more vs. less) between-subjects design, we provided participants with either a seven-paragraph passage to describe the projector (“more information” condition) or seven short sentences (“less information” condition) followed by the picture of the projector. The increase in the amount of information significantly increased the perceived heaviness of the product.

Study 6a examined the complete chain of serial effects: amount of information → perceived heaviness → quality inference → willingness to pay, using a single factor (information: more vs. less) between-subjects design. In the “less information” condition, we used the regular box of a ceiling lamp, whereas in the “more information” condition, we included repetitive information on the front and back of the box. We found that information amount positively impacted perceived heaviness, which further increased perceived quality. The high-quality inference increased WTP for the product indicating a serial mediation effect.

In study 6b, we manipulated associations between weight and quality and found that information amount positively impacted perceived heaviness. There was also an interaction of perceived heaviness and weight-quality association on WTP. Importantly, the indirect effect of information on WTP via perceived heaviness was significant only when people held “the heavier the higher quality” belief; but not when they held “the lighter the higher quality” belief.

Our research contributes to the literatures on product weight, packaging, and lay theories. Also, we provide important insights for manufacturers, retailers, and advertisers about how much information to include on product packaging, advertising messages, and sales presentations.

EXTENDED ABSTRACT

Visual elements of packaging design serve as an important strategic tool for manufacturers and retailers to communicate sensory features of the food product to consumers (for a review, see Krishna, Cian, and Aydinoğlu 2017). However, there is little research on a visual–gustatory correspondence effect as well as its consequences for consumption quantity and subsequent choices. To address this gap, the current study proposed and documented a visual–gustatory correspondence effect whereby the imagery of a food product placed at the bottom (vs. top) of the package façade enhances consumers’ expectations and perceptions of the flavor richness of the food. Moreover, this cross-modal correspondence between imagery location and flavor richness reduces consumers’ consumption quantity and subsequently leads them to choose healthy snacks.

The literature on cross-modal correspondences shows that physical cues of heaviness, such as a heavy (vs. light) container, prompt people to perceive the food contained as being denser (e.g., Piqueras-Fiszman et al. 2011). In addition, past studies suggest the effects of heaviness manifest through both physical touch and semantic priming (Zhang and Li 2012). Since package design conveys a specific meaning to consumers (e.g., a bottom vs. top location signals visual heaviness vs. lightness, Deng and Kahn 2009; Sundar and Noseworthy 2014), we expected that as with physical heaviness, packaging imagery placed at the bottom (vs. top) of a package façade enhances consumers’ taste perception (e.g., flavor richness) (H1). Given that the lower location of a food image enhances perception of flavor richness, we expected this cross-modal perception to, in turn, decrease the quantity of food consumed, since eating rich-flavored food results in satiety, and thus reduced motivation to eat (Rolls et al. 1981) subjects (n=32 and decreased food intake (H2). Moreover, because the feeling of satiety leads consumers to switch to a food of a different flavor (e.g., Inman 2001), we expected that a food image placed at the bottom (vs. top) of the package would result in a post-consumption preference for a healthy (vs. tasty but less healthy) snack (H3). To test these hypotheses, we conducted four laboratory experiments.

In Study 1A, 104 participants were asked to look at a fictitious package of chocolate chip cookies with the cookie imagery located at either the top or bottom of the package façade. Subsequently, they rated their expectations of the cookies’ flavor richness and purchase intentions for the cookie on 7-point scales. As predicted, results showed that participants in the bottom (vs. top) condition expected the chocolate chip cookies to be richer in flavor and indicated higher purchase intentions for the cookies. Furthermore, mediation analysis revealed a significant indirect effect of imagery location on purchase intention through expected flavor richness.

In Study 1B, 194 participants were instructed to sit at a desk facing a liquid crystal display (LCD) screen; three pieces of almond chocolate and a questionnaire booklet were placed on the desk. After reporting their hunger level on a 10-point scale, participants ate all three pieces of the chocolate while looking at the package picture with candy imagery located at either the top or bottom of the package on the LCD screen. After eating all the pieces, participants evaluated the flavor richness of the chocolate on a 7-point scale. As expected, an analysis of covariance (ANCOVA) showed that, after controlling for self-reported hunger level, participants in the bottom (vs. top) condition perceived the chocolate as being significantly richer in flavor.
In Study 2, 155 participants were each given a snack package (containing 40 g of caramel popcorn) with the snack image placed at either the top or bottom of the package after reporting their hunger level on a 10-point scale. Then, we played a 15-minute nature documentary film on a screen and requested the participants to eat as much popcorn as they liked while watching it. After playing the film, we instructed them to stop eating the popcorn and indicate their perceived flavor richness, perceived satiety, evaluation of the documentary, and their dietary restraint on 7-point scales. Moreover, we measured each participant’s consumption by subtracting the remaining amount of popcorn from the initial amount. An ANCOVA revealed that, after controlling for participants’ hunger level, dietary restraint, film evaluation, and gender, the participants in the bottom (vs. top) condition ate significantly less popcorn. Moreover, serial mediation analysis revealed a significant indirect effect of imagery location on consumption quantity through perceived flavor richness and perceived satiety.

In Study 3, 152 participants were each handed a snack package (containing three pieces of chocolate) with the candy image located at either the top or bottom of the package. After looking at the package for 10 seconds, the participants were instructed to eat all three pieces of chocolate, and answer questions about their dietary restraint and demographic information. Furthermore, they chose either a tasty snack (normal chocolate bar) or a healthy snack (chocolate granola bar; pretested to be viewed as a healthier snack than the other option) as a reward for participation. A binary logistic analysis revealed that, after controlling for participants’ dietary restraint and gender, the percentage of healthy snack choices in the bottom condition was significantly higher than that in the top condition.

Through four experiments, we found that the imagery of a food product placed at the bottom (vs. top) of the package façade positively influenced consumers’ expectations and perceptions of the flavor richness of the food, and their purchase intentions for the product (Studies 1A and 1B). However, this cross-modal effect carried over to negatively affect their consumption quantity (Study 2) and even led consumers to subsequently make healthier food choices (Study 3). These results were consistent with H1, H2, and H3. To the best of our knowledge, this is the first study to identify a visual packaging design element that can increase taste perception but decrease consumption quantity. These effects contribute to addressing consumers’ self-control dilemma between short-term benefits (e.g., eating a lot of tasty foods) and long-term benefits (e.g., reducing food consumption for their health).

The Effect of Packaging Typeface on Product Perception and Evaluation

EXTENDED ABSTRACT

Product packaging is generally considered a critical in-store marketing tool because its presence at the point of sale has the potential to convert a browser into a buyer. Previous research has studied package shape (Raghurib & Krishna 1999), size (Scott et al. 2008), and imagery (Deng & Kahn 2009). Packaging typeface is an understudied element.

Typeface is a set of fonts that share common design features. Research in information design has shown that design features of a typeface can yield connotations (e.g., elegance, novelty, potency) above and beyond the denotive message contained in the text (Bartram 1982; Rowe 1982). Thus, typefaces can affect audience responses via the interaction between the connotative meaning of the typeface and the denotive meaning of the text—when the two are consistent (e.g., a “sturdy” font is used for representing “sturdy” professions such as construction work), the perception about the message is strengthened (Foltz, Poltrock, & Potts 1984; Lewis & Walker 1989).

In this research, we focus on the consistency between packaging typeface and the product’s intrinsic or extrinsic cue. An intrinsic (extrinsic) cue, such as product ingredient (brand name), is something that is (is not) essential to the product in that altering it would (would not) change the composition of the product or affect its performance (Rao & Monroe 1989). We hypothesize that, when the typeface’s semantic connotation and the information signaled by the product’s intrinsic or extrinsic cue are aligned (e.g., when both are associated with “naturalness”), persuasion will be enhanced.

Henderson, Giese, and Cote (2004) identify six factors underlying various typeface design characteristics. One of them is “naturalness.” In this research, we are interested in using packaging typeface to promote the product’s health benefit. Our empirical work began with a pretest to identify “natural” versus “unnatural” typefaces. Participants rated a pangram (“The quick brown fox jumps over the lazy dog”), written in 16 different typefaces, on overall liking, naturalness, and legibility. Naturalness was measured by five 7-point scales (organic/geometric, looks typed/looks handwritten, active/passive, slanted/straight, curved/angular; Henderson et al. 2004; α = .83).

We selected SketchFlow Print to represent “natural” font (M = 3.45) and Impact to represent “unnatural” font (M = 2.51), both of which were rated equally likely (4.45 vs. 4.46) and legible (4.24 vs. 4.10). Manipulation checks in the following studies consistently found that the natural font was rated more “natural” than the unnatural font (p’s < .0001).

Study 1 focused on intrinsic cue and used a 2 (fat-free vs. regular yogurt) x 2 (natural vs. unnatural typeface) between-subjects design. The stimuli were two yogurt packages differed on the nutrition information (fat free vs. regular) and the typeface used (natural vs. unnatural). All verbal information on the package was affected by the typeface manipulation. Participants were presented with the package and indicated their overall product evaluation, perceived product healthfulness, and perceived typeface naturalness. The interaction was significant for both healthfulness perception (F(1, 149) = 5.9, p = .02) and product evaluation (F(1, 149) = 4.2, p = .04).

Plan comparisons revealed that, relative to participants who saw the unnatural-font package, those who saw the natural-font package perceived the product to be healthier (M = 5.20 vs. M = 4.32; t(149) = 2.7, p = .008) and evaluated it more favorably (M = 4.65 vs. M = 3.18; t(149) = 3.5, p = .001), however only in the fat-free (vs. regular) yogurt condition.

Study 2 manipulated an extrinsic cue by informing participants that the product was offered by Whole Foods (a store known for selling organic products) versus Meijer (a regional store without such reputation). The stimuli were two cookie packages differed on the store brand and the typeface used. The design and measures followed Study 1. The interaction was (marginally) significant for healthfulness perception (p = .08) and product evaluation (p = .04). Plan comparisons showed that those who saw the natural (vs. unnatural) font perceived the snack to be healthier (p < .0001) and evaluated it more favorably (p = .04), again only in the Whole Foods (vs. Meijer) condition.

The first two studies suggest that the use of a natural (vs. unnatural) font improves product perception and evaluation when the product’s health benefit is made salient by the presence of a consistent intrinsic or extrinsic cue. In addition to product variables, in this research, we also investigate individual variables as potential moderators of the typeface effect. Study 3 examined consumer’s verbal versus visual processing style (Childers, Houston, & Heckler 1985).
Because typeface characterizes textual information, we expect its effect to be stronger for individuals who chronically prefer to engage in verbal processing.

The stimuli were two cookie packages that displayed the natural or unnatural font. After the rating tasks, participants completed the style-of-processing scale (Childers et al. 1985). We averaged the 11 verbal items to form a verbalization index (α = .73; M = 30.23, SD = 4.10). For healthfulness perception, the typeface by verbalization interaction was significant (F(1, 98) = 4.7, p = .03). Furthermore, floodlight analysis using the Johnson–Neyman technique revealed that the typeface effect (i.e., healthfulness perception was higher when the natural font was used) was significant only for participants who scored higher than 29.34 on the verbalization index (B_{pN} = .59, SE = .30, p = .05). For product evaluation, the interaction was also significant (F(1, 98) = 9.3, p = .003). Again, the typeface effect (i.e., evaluation was higher for the natural font) was significant only for those who scored higher than 30.25 on the verbalization index (B_{pN} = .57, SE = .29, p = .05).

The three studies together suggest that packaging typeface conveying the "naturalness" connotation can lead consumers to perceive the product to be healthier and like it better. However, this is the case only when the "healthiness" concept is made salient via the presence of an intrinsic or extrinsic cue, or when the consumer is particularly sensitive to textual information. In this sense, the typeface effect observed is subtle and necessitates careful managerial considerations.

Is Matte the New Black? The Impact of Learned Associations on Perceptions of Food Healthfulness

EXTENDED ADSTRACT

Consumers have learned that unhealthy snacks such as potato chips tend to be sold in glossy packages, whereas healthier snacks such as crackers tend to be sold in matte packages. As a result, consumers who see a snack food package with a matte [glossy] surface will infer greater [lesser] healthfulness of its contents, consume more [less] of it, and be more likely to choose a matte [glossy] package from an assortment if motivated to engage in healthful [tasty] eating.

Study Summaries

In Study 1, we conducted store checks in six retail outlets selling consumer packaged foods in a major metropolitan market in the U.S. We counted the number of glossy and matte shelf facings for two product categories—crackers and potato chips, which are generally believed to be more and less healthy prior research (Deng & Kahn, 2009). A total of 2,656 packages were classified in this manner. We found the majority of potato chips on store shelves were packaged in glossy (76.8%) rather than matte packaging, whereas a minority of crackers were packaged in glossy (9.5%) rather than matte packaging (χ²(1) = 1387.12, p < .001). The results support our contention that consumers have been repeatedly exposed to snack food packaging that creates and reinforces associations regarding package type and healthfulness (i.e., matte = healthier, glossy = less healthy).

Study 2 was a survey conducted online survey among Amazon MTurk participants (N = 211, median age = 32, 47% female). Participants believed that potato chip (versus cracker) packages were more likely to have a glossy surface (M_{potatochip} = 3.81, M_{cracker} = 2.48, paired t(210) = 15.24, p < .001, Cohen’s d = 1.05). Participants estimated that 65.3% of potato chips [38.7% of crackers] were sold in glossy rather than matte packaging (paired t(210) = 13.81, p < .001, Cohen’s d = 0.95).

In Study 3, 42 undergraduates (N = 42, median age = 20, 40% female) completed an Implicit Association Test (IAT; Greenwald, McGhee, & Schwartz, 1998), which assessed the relative strength of associations between healthfulness concepts and package type indirectly. Participants categorized pictures of healthy and unhealthy foods and glossy and matte packages that appeared in the middle of the screen. If it is true that participants have learned to associate healthy foods with matte packaging and unhealthy foods with glossy packaging, they should categorize the visual stimuli more quickly when the category labels are congruent, rather than incongruent. As predicted, the data yielded a positive D-score (D = .171, SD = .36, t(39) = 3.02, p = 0.004, 95% CI_{D} = [0.06, 0.29]), indicating learned associations between matte packaging and healthy foods and between glossy packaging and unhealthy foods.

Study 4 measured the effects of packaging gloss on healthfulness inferences. 156 MTurk participants (median age = 32, 51.3% male) viewed a matte or glossy package of potato chips. Participants reported how healthy, fattening [reverse-scored], greasy [reverse-scored], oily [reverse-scored], and high calorie [reverse-scored] the chips were (order of items randomized; on 1 to 100 scales, α = .89). An ANOVA on healthfulness perceptions as a function of package type was significant (M_{mattte} = 51.04, M_{gglossy} = 39.94, F(1, 154) = 9.01, p = .003; η² = .07).

In Study 5, students (N = 203, median age = 20, 39.9% female) in a purported taste test were given a caloric goal (to put about 50 calories of chips in a bowl for tasting). Participants poured out (M_{mattte} = 11.77 g, M_{gglossy} = 10.21 g, F(1, 201) = 4.86, p = .028; η² = .024) and consumed fewer potato chips from a white glossy versus matte package (M_{mattte} = 5.63 g, M_{gglossy} = 3.85 g, F(1, 201) = 6.74, p = .001; η² = .033).

Study 6 was a field study in which a display containing 36 packages (18 matte packages, 18 glossy packages) of single serving snack foods was attached to each of two food trucks on the campus of a large state university (one food truck which sold primarily hamburgers and the other which sold primarily salads) for 25 days. We expected that patrons of the salad truck (versus burger truck) would be more likely to purchase the snacks packaged in matte (versus glossy) packaging, exhibiting a congruence effect. That is, consumers who choose to buy their lunch at the hamburger (versus salad) truck are, relatively speaking, likely more motivated by taste (healthfulness). If so, then hamburger (salad) truck patrons should be more (less) likely to select a snack packaged in glossy packaging, in accord with their taste (health) motivations for consumption. Results from a linear mixed model showed that, compared to patrons of the burger truck, patrons of the salad truck purchased a lower proportion of glossy packs (M_{salad} = 33.96%, M_{burger} = 72.72%, b = -.37, se = .06, t = -6.33, p < .0001; 95% CI: -.48 to -.25).

Contributions

This research is the first we are aware of to demonstrate how healthfulness inferences are influenced by package gloss, an easily neglected and relatively subtle sensory cue. Theoretically, current findings add to the product packaging research, especially the relatively scares research in packaging surface and materials. Managerially, our results suggest that snack food marketers can alter expectations about their products by manipulating glossiness dimensions of their packaging. For example, marketers might enhance sales of their products by strategically using matte packaging for customer segments seeking health-related consumption benefits. Additionally, marketers of diet could use glossy packaging to enhance perceptions of satiation or indulgence – which may contribute to weight control goals.

SESSION OVERVIEW
Much research has examined the words people use when talking in consumption-related contexts (cf. Berger 2014 review). But when it comes to consumer language, most research is constrained to static contexts such as advertising, online reviews, or sales pitches broadcasted from one to many. Considerably less attention has been paid to the interactive conversations happening among consumers, or between consumers and firm agents in digitally mediated, text-based interactions. How can we gain wisdom from consumer conversations? This session integrates work examining language and paralanguage to help address this question. Can paralinguistic cues in text messages shift perceptions towards conversation partners, including “artificial” conversants (e.g., AI and chatbots)? Could linguistic signals of employee empathy or involvement boost customer satisfaction? This session examines these and other questions as it presents new insights on language and paralanguage in consumption-related conversations.

First, Bluvstein, Zhao, Barasch, and Schroeder investigate how seemingly incidental features in customer service conversations can humanize agents, whether those agents are human or machine (e.g. AI chatbots). They demonstrate that observing conversational “mistakes” (e.g., typographical errors) can make chatbots seem warmer, more human, and increase the sharing of personal information.

Second, Ordoñes, Grewal, Grewal, and Sarantopoulos demonstrate that dynamic shifts in a service agent’s linguistic style from dominant to submissive language have a positive effect on the customer’s linguistic negativity and judgments that the issue was satisfactorily resolved.

Third, Luangrath, Peck, Barger, and Haynes examine mimicry in text-based conversations and find that people mimic the nonverbal paralanguage (e.g. emoticons, ALL CAPS) of their conversation partner. This behavior is mediated by empathy and, therefore, does not occur when responses will not be seen by its recipient. The authors further reveal a cross-modal visualization effect such that even visual and tactile TPL facilitate auditory processing of messages.

Finally, Packard and Berger demonstrate how linguistic concreteness shapes customer satisfaction. Agents speak more concretely (vs. abstractly) are seen as more personally involved in the customer’s specific needs, leading to heightened customer satisfaction, purchase intentions, and real post-interaction expenditures.

In sum, these papers highlight how language and paralanguage enhance social interactions. We hope that this session will attract a wide audience of ACR attendees with interests in social influence, language, interaction modality, consumer experience, machine or AI agent interactions, and those interested in theory domains ranging from dialogical interaction to communication theory, and psycholinguistics to information processing.

Hello! How May I Helo You? How Written Errors Can Humanize a Communicator

EXTENDED ABSTRACT
Written communication is often dehumanizing. The conversational counterpart is removed in space and/or time, which can create detachment (Chafe, 1982). Furthermore, text lacks critical paralinguistic cues (e.g., voice) which convey the presence of a human-like mind (Schroeder & Epley, 2015, 2016). As a result, text-based communication has been shown to reduce consumer trust, engagement, and willingness to share information or accept advice from an agent (Powers & Kiesler. 2006; Kiesler et. al, 2008; Waytz et. al, 2014). Yet, firms are increasingly conversing with consumers in writing, such as through chat platforms. In some cases, the conversational counterpart is a human; in other cases, it is artificial intelligence (AI).

Researchers have explored many factors of AI agents that may influence users’ perception of their humanness. Some attempts suggest anthropomorphizing the agent by adding seemingly superfluous humanlike features of the agents, such as gender, face and name (Scassellati, 2004; Hoffmann et. al, 2006; Krämer, Lam-chi, & Kopp, 2009). Other efforts emphasize designing algorithms that can interact with humans flawlessly, with no errors. However, according to established psychological theories, to be truly human-like means to make mistakes (Aronson et al., 1966).

We propose a novel research angle for humanizing text: that making a written error and then correcting it should reveal a human-like mind behind the words. In three experiments, we test specifically whether errors lead readers to infer greater humanness from an ambiguous communicator, and whether this leads to behavioral consequences.

First, Experiments 1 and 2 examined whether people who read a written communication script from a customer service agent would share more personal information when the agent made a typographical error (“May I helo you?”) and subsequently corrected it (“Sorry.. Help you”) than when it made no error. To compare the humanizing value of an error with other humanizing cues, we asked 263 online participants in Experiment 1 to examine a message written by an online chat agent. In addition to manipulating whether or not the agent made an error, we also manipulated features of the agent, including
the agent’s gender and whether the agent’s photo was a real human or avatar. Participants then rated the humanness of the agent and indicated their likelihood to share personal information with it and use it again in the future.

As expected, participants perceived the agent who made an error as more human (F(1, 258) = 54.85, p < .001, η² = .17). The gender and whether or not the agent made an error did not statistically interact with any other factor to influence humanness perceptions. The error also led participants to report significantly greater likelihood to share information with the agent (F(1, 258) = 6.42, p = .01, η² = .02), and to use it again in the future (F(1, 259) = 8.69, p = .003, η² = .03). Perceived humanness mediated the effect of error on both intention to share information (b = 0.66, SE = .13, 95% CI [0.41, 0.93]) and likelihood to use it in the future (b = 0.88, SE = .14, 95% CI [0.61, 1.17]).

Experiment 2 (n=402 online participants) used a similar paradigm to measure participants’ intention to share personal information using more concrete items (e.g., phone number), as well as the impact of error on social perception of the agent (i.e., warmth and competence). We manipulated the presence of a typo and agent photo with a 2 (photo: avatar vs. human) × 2 (error: present vs. absent) between-subjects design.

We replicated the effect of error on perceived humanness (F(2, 398) = 59.80, p < .001, η² = .13). Moreover, while the effect of error on sharing behavior was only directional (F(1, 398) = 2.24, p = .13, η² = .006), there was a significant indirect effect of experimental condition on sharing behavior via perceived humanness of the agent (b=.86, SE=.17, 95% CI [0.54, 1.25]). We further found that the error increased the agent’s perceived warmth (F(1, 398) = 10.55, p = .001, η² = .03), but did not affect the agent’s perceived competence (F < 1.1), and that humanness perception of the agent mediated the effect on warmth perception (b=.55, SE=.82, 95% CI [0.40, 0.72]).

Experiments 1 and 2 only included the presence and correction of a typographical error together. To better understand whether it is the error itself or the correction of the error that influences perceptions of humanness, Experiment 3 (n=391 lab participants) included a new experimental condition where the agent made but did not correct its error (uncorrected-error) in addition to the previous two conditions (no-error, or corrected-error). Moreover, to increase realism, this experiment introduced a real time chatting experience, where respondents interacted with a customer service agent who asked them personal questions (“Have you ever cheated on an exam?”).

Results revealed a significant effect of error on perceived humanness (F(2, 388) = 4.58, p = .01); specifically, humanness perception was greater in the corrected-error condition than the uncorrected-error (p =.01) and the no-error conditions (p < .01). In addition, the effect of error on sharing personal information was marginally significant (F(2, 388) = 2.78, p = .06), whereby participants shared more in the corrected-error condition versus the no-error (p = .03) and the uncorrected-error (p = .06) conditions. There was no difference between the uncorrected-error and the no error conditions for both humanness perceptions and sharing behavior (ps > .6). These results suggest that the error alone is not enough to activate these effects; rather, it is the act of correcting one’s error that reveals the presence of a conscious mind.

In aggregate, these experiments suggest that the way in which communicators write their words---such as making and then correcting a spelling error---can actually influence readers’ predictions about whether a communicator is human. While prior research has mostly examined humanizing cues in spoken language, we contribute to a relatively new stream of literature exploring how written language can be humanized. Our results also provide insight into when people might share personal information, with potential implications for consumer privacy.

How Concrete Language Shapes Customer Satisfaction

**EXTENDED ABSTRACT**

Consumers tend to agree that if there’s one thing that companies could always do better, it’s customer service. Accordingly, academics and marketing practitioners are greatly concerned with what they can do to improve the sales and service experience (e.g. Rust & Chung, 2006; Zeithaml, Berry, & Parasuraman, 1996). One of the most important things an employee can do is signal that they are personally involved in the customer’s needs (Smith, Bolton, & Wagner, 1999).

But outside of actually saying “I care” are there more natural ways that employees can signal their personal interest in the customer’s needs?

This paper examines whether the words they use can help. Specifically, we suggest that speaking more concretely can make customers more satisfied and more likely to purchase. Consider a customer who’s interested in buying a shirt. While conversing with the customer, the salesperson might refer to the object in a very concrete way (e.g., “the shirt”), a very abstract way (e.g., “that”) or somewhere in between (e.g., “the top” or “the clothing”).

We suggest that these small linguistic variations can have an important impact on customers beliefs and behaviors. People tend to think about and describe themselves concretely, yet think about and describe others more abstractly (Eyal and Epley 2010). If concreteness can generate social cognitions, as we suggest, then agents that speak more concretely (less abstractly) about the customer’s issues might signal that they are cognitively “closer” to the customer’s personal needs. If so, using concrete language should boost satisfaction because it signals that the agent is personally involved and attentive to the customer’s specific needs (Smith et al. 1999). More satisfied customers should have more positive intentions towards the firm (Singh and Sirdeshmukh 2000; Smith et al. 1999), and, in turn, may actually spend more with them.

We test these possibilities in four studies combining textual analysis of over 1,000 real customer service interactions in the field with lab experiments.

Study 1 used natural language processing (NLP) to examine 200 customer calls to an online fashion retailer. We used a bootstrapped extension of the MRC Psycholinguistic Database (Paetzold & Specia, 2016) to score over 85,000 English language words for their concreteness. Consistent with our theorizing, agents that used more concrete language on the call were perceived as more satisfied with the agent in an end-of-call survey (b = .17, t = 2.36, p = .02). This holds even after controlling for customer, agent, interaction, language features (b range = .08-.13, all ps < .01). A dynamic examination of the time-series of conversational turns using vector auto-regression confirmed that the importance of employee concreteness also persists after accounting for temporal shifts in customer concreteness and other linguistic features.

Study 2 analyzed nearly 1,000 customer service emails to a consumer durables retailer using the same NLP methods as Study 1. These simpler, text-based email interactions help rule out the possibility that vocal cues or other interaction dynamics drove the results from Study 1. This study also asks whether concreteness impacts purchase behavior. Regression analysis supports the predicted relationship. Customers spent more following calls in which the agent used more concrete language (b = .08, t = 2.86, p = .004). This rela-
theroship was robust to a range of controls similar to those included in Study 1.

While the first two studies are supportive, one could wonder whether the relationship is truly causal in nature. To test this and examine the effect’s mechanism, Study 3 (n = 88 student participants) directly manipulated linguistic concreteness and measured its impact on satisfaction, behavioral intentions and social perceptions. Participants received one of two versions of a pre-tested customer service scenario that differed only in the concreteness of two words used in the employee’s response (e.g., “I can cancel them” vs. “I can cancel the shoes”). As predicted, using more concrete language increased customer satisfaction (F(1, 147) = 9.53, p = .002) and purchase intentions (F(1, 147) = 3.52, p = .06). Further, consistent with our theorizing, mediation analysis confirmed that this relationship was driven by perceptions that the employee was more closely engaged with the customer’s needs (satisfaction indirect effect = .22, 95% CI [.08, .38]; purchase intentions indirect effect = .24, 95% CI [.09, .41]). This study also rules out mimicry, processing fluency, and language typicality as alternative explanations.

Study 4 replicates and extends the causal tests of Study 3, recognizing that linguistic concreteness can vary in different ways. We examined a series of subtle manipulations of nouns, adjectives, and verbs that each slightly increase concreteness, and measure their impact on satisfaction and purchase intentions. Participants received one of six versions of an employee saying they’d help them find a t-shirt in grey. The pattern of results over the six conditions (linear effects coding) replicated prior studies, finding that concreteness increased customer satisfaction (b = .10, t = 4.49, p < .001) and purchase intentions (b = .09, t = 4.28, p < .001). Mediation analysis confirmed that perceived involvement mediated concreteness’ effect on customer satisfaction (indirect effect = .08, 95% CI [.05, .12]) and purchase intentions (indirect effect = .07, 95% CI [.04, .10]).

This research makes three main contributions. First, we deepen understanding of how language shapes consumer behavior. We demonstrate the important role of linguistic concreteness and the underlying process that drives its impact.

Second, we extend linguistic construal to the domain of social perceptions. While most work on concreteness examines the impact of concreteness on cognition, the present research reveals that people generate social cognitions through the language used by another person.

Third, from a practical perspective, these results have clear implications for improving marketing interactions with customers. Small shifts in the language customer service people use can improve a variety of important downstream marketing outcomes.

Nonverbal Mimicry of Textual Paralanguage

EXTENDED ADSTRACT

This research investigates mimicry of text-based nonverbal communication, termed textual paralanguage (TPL). TPL refers to the written manifestations of nonverbal audible, tactile, and visual communication (Luangrath, Peck, and Barger 2017). Currently in consumer research, there is a growing interest in gaining insights from text-rich data (Humphreys and Wang 2018; Moore and McFerran 2017, Packard and Berger 2017; Villarroel-Ordones et al. 2018). Since consumer and brand messages are laden with TPL, we approach the study of language by focusing on how nonverbal cues are expressed and mimicked in text conversations.

It is a natural human tendency to mimic the mannerisms, facial expressions, and postures of those with whom we interact. Previous research into what has been dubbed “the chameleon effect” demonstrates that we mimic nonverbal cues when communicating in-person (Chartrand and Bargh 1999). Here, we investigate whether consumers mimic nonverbal cues when communicating online via text, so we ask: do models of behavioral mimicry apply to nonverbal textual mimicry? For example, if a consumer were to read a brand’s tweet “Best. Sale. Ever.”, an instance of auditory TPL, is the brand likely to reply with TPL? Whereas in-person mimicry is thought to occur due to a desire to affiliate (Lakin and Chartrand 2003), we expect nonverbal textual mimicry to operate via empathy.

Study 1a examines the extent to which TPL affects empathy. Amazon MTurk participants (N=309) were asked to evaluate a tweet: “To celebrate one week of healthy living, we’re offering 20% off everything [EVERYTHING, woot woot, :)]” TPL was manipulated at the end of the tweet. Participants responded to “How much does the message help you empathize with the writer?” Results indicate that TPL facilitates empathy (M_{NoTPL} = 3.01, M_{TPL} = 3.65, F(1,308) = 4.40, p = .037). In study 1b students (N=430) were presented with eight tweets that varied in positivity/negativity, sarcasm, and the type of TPL incorporated. Participants empathized more with the writer when TPL was used (M_{NoTPL} = 4.23, M_{TPL} = 5.14, F(1,429) = 38.08, p < .001). Across instances of TPL, message content, message valence, and diverse populations, we demonstrate that TPL affects the degree to which a reader can empathize with a message.

In Study 2, we examine whether TPL is mimicked. Participants were asked to consider the following scenario: “You heard that one of your favorite music groups will be coming to perform in your city. You would really like to attend, and you decide to send a message and invite your friend, Pat, to attend the concert with you. This is Pat’s text message response: I’m sorry I already have plans that day. [*sigh*] Please write a follow-up response to Pat.” Manipulation of TPL occurred with the inclusion/omission of “[*sigh*]”. Participants were much more likely to respond with TPL when the initial text contained TPL (β = .083, t(722) = 3.44, p < .001). Moreover, individuals high in empathetic concern were more likely to respond with TPL (β = -.094, t(722) = 3.82, p < .001), indicating the importance of empathy in TPL mimicry.

In Study 3 we expect that TPL will not be mimicked when the message response will not be viewed, since in-person behavioral mimicry tends to occur more frequently in the presence of an inter-actant partner. This study is a 2 (TPL vs. No TPL) x 2 (viewable vs. not viewable) design. Participants were shown a brand tweet either with or without TPL. Then, participants were asked to create a tweet about their positive experience with the brand, and told “the current algorithm on Twitter would [NOT] allow the brand to see the tweet that you create.” Results reveal a significant interaction (β = 1.06, Wald^2 = 4.187, p = .041) such that individuals mimic TPL the most when it will be seen by the brand.

Study 4 explicitly tests the empathy account to nonverbal mimicry. Participants (N=246) were asked to view and respond to a tweet on their mobile device: One of your favorite restaurants, The Midday Café, is opening in your neighborhood. The café tweets the following: “Come visit our new location on Madison Street. Opening soon (soooooon, [smiling emoji], [high five emoji]).” Results demonstrate that TPL facilitates empathy (β=1.04, SE=1.21, p < .001). Those who viewed the initial tweet with TPL were also significantly more likely to respond with TPL (β = -.30, SE =.11, p = .005). Mediation analysis reveals a significant indirect effect of TPL on mimicry via empathy [.08, 95% CI .02, .16]. Thus, TPL helps facilitate empathy, which encourages mimicry.
Study 5 further demonstrates this causal process by using a concurrent double randomization design to manipulate the mediator (Pirlo and MacKinon 2016). Empathy was manipulated among participants prior to them viewing a text message from a friend with TPL also manipulated. Manipulated empathy affected the amount of textual paralanguage used in response ($F(1,183) = 3.53$, $p = .06$), again illustrating empathy’s role in facilitating TPL mimicry.

Furthermore, Study 6 demonstrates TPL increases cross-modal visualization, which facilitates empathy, and results in mimicry of nonverbal expressions. Undergraduate students ($N = 156$) were asked to respond to a brand tweet as in study 4. Participants rated a series of statements regarding the message: “I feel like I can hear how this would be spoken” (auditory), “I can imagine the facial expression that the speaker would have” (visual), and “I feel physically close to the sender of this message” (tactile). A serial mediational process demonstrates that all types of TPL facilitate auditory visualization, thereby increasing empathy and mimicry [0.1, (5% CI 0.01, 0.023). This research suggests that people engage in nonverbal mimicry in online textual communications, and, unlike behavioral mimicry, this phenomenon occurs due to heightened empathy. We find that mimicry of TPL does not occur when responses will not be seen, and that a cross-modal visualization effect exists such that even visual and tactile TPL facilitate auditory processing of messages. In short, textual paralanguage fundamentally communicates emotion, and we demonstrate here that the power of TPL is in its ability to make a message resonate with a consumer.

**The Impact of Dialogue Dynamics in Online Service Resolution**

**EXTENDED ABSTRACT**

In the “always on” digital landscape, responsiveness is critical, and customers seek out platforms that will enable them to obtain a response, often in writing, to establish proof of their agreement or grievance. Many firms thus invest heavily in improving their text-based customer service, such that these investments are expected to increase by 48% by 2020 (Berg, Gilson, and Phalin 2016).

The present research uses a dialogical approach (Kent and Taylor 2002), which considers how service interactions are contingent on relationships of control and trust between speakers, to investigate how FLEs can use language to handle negative emotion in customer complaints, and therefore contribute to service resolution. We make three main contributions.

First, we advance literature on complaining behavior by assessing the effect of negativity in customer complaints language on service resolution. Negative customer language is both harmful to the firm and hard for firm representatives to deal with (Henkel et al. 2017), however its effects have not been studied beyond face-to-face interactions.

Second, we extend the literature on digital customer service by assessing the mitigating role of FLEs’ dominance language, contingent on the strength of the customer complaint. Recent research suggests that FLEs should take control of a customer complaint by using more action words (Marinova, Singh, and Singh 2018). We go a step further to posit that FLEs’ language dominance can mitigate the influence of more negative complaints on service resolution.

Third, we advance the literature on service resolution by studying FLEs use of linguistic style matching (LSM). Greater LSM, or similarity in people’s uses of function words, signals verbal synchrony, prompting perceptions of trust (Scissors, Gill, and Gergle 2008). We propose that FLEs can leverage LSM to mitigate the effects of strongly negative customer complaints.

**Study 1** uses social media data from Twitter and Facebook, examining 1,142 complaint-initiated dialogues between a customer and FLE’s from retail accounts. For our dependent variable, service resolution, we rely on crowdsourcing, such that for each dialogue, we asked three independent members of Amazon Mechanical Turk to read it and indicate, “Do you think the solution offered met customer needs?” (1 = “definitely not,” 5 = “definitely yes”). Then, we measure the customer sentiment strength of each dialogue (i.e., how negative was the complaint) by using SentiStrength, a computerized text analysis tool (Thelwall, Buckley, and Paltoglou 2011). To assess FLEs’ use of dominance in their language, we rely on Mohammad’s (2018) dictionary of dominance, which lists 20,007 English words and their dominance scores, ranging from 0 (low) to 1 (high). Finally, we derive the degree of linguistic style matching (LSM) between the customer and FLE by relying on LIWC dictionaries (Tausczik and Pennebaker 2010), which are widely applied in marketing research.

Our modelling approach includes brand fixed effects and we standardized all the predictor variables. We control for several dialogue characteristics such as compensation, apology, product or process complaint, number of messages, use of pictures, etc. We specified three hierarchical models. As predicted, greater sentiment strength in customer complaints has a negative effect on service resolution ($β = .06; SE = .02, p < .05$). We also find a significant main effect of FLE dominance ($β = -.07; SE = .03, p < .05$). The customer sentiment strength × FLE dominance interaction is marginally significant ($β = .04; SE = .02, p < .10$). We also find a significant customer sentiment strength LSM interaction ($β = .08; SE = .02, p < .001$).

With Study 2a and b, we replicate these findings in two controlled experiments that affirm that the effects in Study 1 are causal (vs. correlational) in nature. In Study 2a and 2b, 394 and 395 MTurk workers respectively participated in two surveys for nominal payment. Both studies used a 2x2 between subjects design. We used identical dialogues from study 1 and only manipulated the level of sentiment strength, FLE dominance and LSM. MTurk workers reported the extent to which they believed that “the solution offered by the employee met customer needs” (1 = “strongly disagree,” 5 = “strongly agree”). Both study 2a and 2b corroborated the findings of Study 1.

In Study 3, we investigate a firm-owned, live chat platform maintained by a Fortune 500 consumer goods firm. We study both the text-based interactions on this platform and consumer responses to a post-service survey. We use the same operationalizations as in Study 1 for the linguistic predictor variables. The dependent variable is the customer response to the survey question, “Did we offer solutions that met your needs?” (1 = “strongly disagree,” 5 = “strongly agree”). We also controlled for interactions that started with a chatbot rather than with a live agent, and the severity of the complaint. The results support our assertions. Greater customer sentiment strength has a negative effect on service resolution ($β = -.18; SE = .06, p < .01$); and we find a significant positive main effect for FLE dominance ($β = .14; SE = .07, p < .05$) and a significant negative main effect for LSM ($β = -.18; SE = .07, p < .01$). Furthermore, the customer sentiment strength × FLE dominance interaction is significant ($β = .11; SE = .06, p < .10$). We also find a significant customer sentiment strength LSM interaction ($β = .14; SE = .07, p < .05$).

These findings support our prediction that customer complaints with greater sentiment strength result in problems that are harder for FLEs to resolve. The effect of customer sentiment strength is moderated by FLE dominance: when customers express strong or moderate sentiments, a more dominant FLE can be more successful in meeting those customers’ needs. Greater similarity in the language
used by FLEs while handling customer demands also mitigates the effect of greater negativity on customer complaints. Specifically, for customers expressing neutral or weak sentiment strength, lower LSM between the customer and FLE can be more successful, but for customers expressing stronger sentiment strength, a greater degree of LSM is more effective.

Hello! How May I Helo You? How Written Errors Can Humanize a Communicator

Nonverbal Mimicry of Textual Paralanguage

How Concrete Language Shapes Customer Satisfaction

The third and fourth papers examine the role of human-computer interaction in shaping brand perception and product choice. Chung and Jun investigate how AR-integration of digital products into a consumer’s physical environment affects consumer experience. They find that AR enhances self-brand connection for low-involved consumers. They further provide evidence that this improved self-brand connection is driven by a heightened consumer perception of the brand as communal rather than exploitative. Finally, Yang and colleagues examine how shopping by voice differs from the online shopping that is navigated by clicking or typing modalities. They find that that shopping by voice leads consumers to select more recommended products, compared to other modalities. They also identify the underlying mechanism for this discrepancy, which is voice shopping increases perceived socialness, which induces compliance behavior.

Our session contributes to the conference by documenting a range of unexplored expression modalities in research on consumer-technology interactions, a burgeoning area of research drawing on theory and methods from computer science, psychology, and design. We believe the session will spur the consumer researchers who are interested in innovations, consumer-technology interactions, and experiential consumption to seize the opportunity to further contribute foundational research in this growing and impactful research area.

**Horizontal Touch Interfaces and the Illusion of Discrete Content**

*EXTENDED ABSTRACT*

As computers have shifted from desktop and laptop computers to tablets and smartphone, interfaces have likewise shifted to direct-touch modalities where consumers directly interact with the content under their fingers. This has created a sea-change in the organization of e-commerce information (Wang, Malthouse, & Krishnamurthi 2015), as sites adapt to differing screen sizes and the lack of a mouse or other indirect pointer. Touch interfaces have been shown to affect choice (Shen, Zhang & Krishna 2016) and alter information salience (Brasel & Gips 2015) when compared to non-touch interfaces. The largely vertical orientation of smartphones and tablet screens in comparison to the horizontal layout of traditional computer screens create new design considerations for how information can be presented. Swiping between pages has become a ubiquitous interface gesture, but horizontal swiping has received little exploration in the interface literature (Kerckhove & Pandelaere 2018; Dou & Sundar 2016).

In this paper, we argue that moving left or right between ‘panes’ of information via swiping creates a different cognitive structure than vertical scrolling. This pane-switching creates a natural break-point in the information, both visually and in cognitive processing, suggesting that the information in separate panes is somehow discrete or separate from information in other panes. This is consistent with tabbed web-browsing suggesting separate source pages as users move horizontally across tabs (Warr and Chi 2013). This should increase the amount of perceived information contained within a site, even if the amount of information is held constant. In addition, if information in horizontal panes is considered more separate or discrete when compared to information presented vertically, reviews may be seen as more independent from the storefront, product specifications may
be viewed as more accurate, and consumers may feel they have processed more information and thus be more confident in their choices.

In Study 1, 104 laboratory participants used an Android Tablet to shop for a pair of noise cancelling headphones. In the Horizontal condition, the information for each pair of headphones was separated into four “panels” of information that could be swiped between left-to-right: Description, Specifications, Customer Reviews, and Ordering Information, each one tablet screen long in vertical length. In the Vertical condition, the four panels of information (with the same content) were arranged vertically and scrolled top-to-bottom; the information was kept one tablet screen wide in horizontal width. The participant could move between the four pairs of headphones either via a vertical menu bar running down the left of the screen in the Vertical condition, or a horizontal menu bar running across the top of the screen in the Horizontal condition. Results show that participants felt the Horizontal design site contained more information than the Vertical design site (5.7 vs 5, p < .05), and reporting evaluating both more products (3.4 vs 2.9 p < .05) and more of the information (85% vs 72% p < .01) when making their choice. Consistent with predictions, Horizontal participants also rated the product reviews as significantly more trustworthy and objective than the Vertical orientation participants (p < .05), and predicted the product specifications were marginally more accurate as well (p < .10). These results combined to increase overall choice confidence and predicted product satisfaction for participants in the Horizontal condition versus the Vertical condition.

In Study 2 (120 participants, similar stimuli to Study 1), for a cleaner test of the touch interaction and to explore whether an effect of orientation remained even if information in both orientations was similarly ‘paneled’, smooth scrolling was disabled so the only way to move between information was either horizontal or vertical swipes that would move a full panel of information at a time. While the Horizontal-vs-Vertical manipulation’s effect on perceptions of the amount of information available and perceived independence of reviews was reduced compared to study 1 (roughly halving in measures of effect size and power), the results remained significant (both p < .05), reinforcing that directionality plays as much of a role beyond just information compartmentalization via paneiling. Respondents also rated the products as more varied when explored via the Horizontal versus Vertical menu bar (4.6 vs 3.8, p < .05). Participants in the Horizontal condition also recalled visiting significantly more panels of information in comparison to the Vertical orientation (similar to perceptions of information completeness in Study 1) when video evidence revealed there was actually no significant difference in the number of visited panels. This pattern of results is consistent with horizontal information paneiling creating a higher salience of breaks between information, elevating perceptions of overall information and information independence.

In conclusion, touchscreen e-commerce sites that use horizontal panels of information that the user can swipe between (versus vertical information structures) create perceptions of discrete breaks between panels of information. This makes reviews appear potentially more independent, while increasing perceived accuracy of product specifications. It also increases the number of alternatives considered and artificially inflates perceptions of the amount of information considered. Future work could explore whether this effect may decrease with habituation, as horizontal swipes are a relatively recent addition to the e-commerce interface lexicon. It may also be useful to explore whether horizontal panel order leads to bias in product information processing, as other applications (such as dating apps) are creating a haptic language where right-swipes are positive and left-swipes are negative.

Good Buzz, Bad Buzz: Using Vibrotactile Feedback to Shape Consumer Choice

EXTENDED ABSTRACT

Nearly all consumers now carry a vibrating mobile device. Aside from the vibrating mobile phones and tablets many of us carry with us, an increasing number of consumer products have integrated vibrotactile feedback. For instance, the clip-on Lumo Sensor vibrates when its wearer begins to slouch (Peppet, 2014), the HAPIfork vibrates if the user is eating too quickly (Green, 2018), and the Fitbit wristband vibrates when a user reaches a fitness goal (Vanhemert, 2015). Despite the increasing ubiquity of devices producing vibrotactile feedback, rigorous research investigating how users process this feedback, and how it affects their decision making, is unclear.

Mechanical vibration, such as that emanating from a mobile phone, generates traveling waves of energy across the surface of the skin. Information from the skin, i.e. periphery, is carried to the spinal cord on individual nerve fibers, then to one or more second-order neurons which interface with the brain where the stimulus is processed. Tactile thresholds can be extraordinarily small with some people able to feel vibratory stimuli as minute as 250 Hz on the palm of the hand (Gescheider, Capraro, Frisina, Hamer, & Verrillo, 1978). In parallel, consumer research has begun to underscore the importance of haptic properties of consumer goods (Peck & Childers, 2003) and communications (Peck & Wiggins, 2006), as well as their impact on purchase intention, donation behaviors, and feelings of ownership and endowment (Peck & Shu, 2009; Shu & Peck, 2011). Adding to this stream of research, Brasel and Gips focus on the touch-aspects of computer interfaces (Brasel & Gips, 2014a). Their findings suggest that the physical interaction with touch screens enhances consumers’ sense of psychological ownership and endowment.

While there is evidence that the length of a stimulus can have an effect on the perceived intensity (Gescheider, Berryhill, Verrillo, & Bolanowski, 1999), measures more relevant to consumer behavior such as pleasantness and reward as well as the downstream consequences on economically relevant outcomes (such as market basket size) have been missing in previous studies. Similarly, although one study using infants hints that vibration may be a potent reinforcer (Schaefer, 1960), it remains unclear whether and how mobile device vibrations modify behavior in adults. Finally, although no study has examined use of vibration as a reward in healthy adults, a study using clinical population suggests that vibration may have long-term effects in modifying behavior (Bailey & Meyerson, 1969). Inspired by this line of prior work, the current research is specifically designed to provide new insight into the perception and influence of vibrotactile feedback on consumer decision making.

In Study 1, one hundred and fifty participants were recruited via Amazon Mechanical Turk. Participants were asked to click buttons that produced a vibration of a particular duration, and then self-report their perceptions. We also assessed a broad range of potential control variables at the end of the study, including general mobile technology usage behaviors (such as the usage of vibration features), sensation seeking, need for touch, and experiential thinking.

We find that reward perceptions vary according to vibration duration $F(3,147)=6.52, p<.001$. Specifically, vibrations of either 400 ms or 800 ms were perceived as significantly more rewarding than all other durations (all $p<.01$). The manner in which responses varied also appeared to be construct-dependent. For instance, we find that the relationship between vibration duration and perceived reward forms an inverted-u shape, with reward perception peaking around 400 ms. Notably, very short vibrations, e.g. 25 ms, or very
long vibrations, e.g., 3200 ms, were reported as punishing rather than rewarding. In examining the relationship between phone usage and other dependent variables, several theoretically and practically important relationships emerged. Higher mobile phone use positively correlated with both sensation seeking (r=17, p<.05) and need for touch (r=.19, p<.05). Positive perception of vibration feedback also covaries as a function of participant traits: Participants who rated the vibrotactile feedback as more rewarding, also scored higher on measures of impulsivity (r=.42, p<.001) and experiential thinking (r=.36, p<.001).

Our first study demonstrated that vibrations of certain durations are perceived as rewards. Given that rewards have been consistently shown to affect motivated behavior (for review, see Papes, Barsalou, & Press, 2015), it follows that vibration feedback could be used to modify behavior. Building on this prior work, Study 2 we presented one hundred and fifty participants with a “Box Task”. This task presented two boxes, with a button below each that adds an item to its respective box. These boxes resembled prototypical online shopping carts. Participants were instructed to press either button as many times as they liked to add items during a set 1.5 minute timeframe. Adding items to Box 1 produced a vibration (400 ms), while adding items to Box 2 did not. As predicted, we find that participants added more items to the vibration-producing box (M=14.69) than other box (M=10.71) that did not produce a vibration

F(2,148)=4.08, p<.05. We also replicated the previously observed negative quadratic-shaped relationship between vibration duration and perceived reward. Together our data strongly support the notion that specific time-durations of vibrotactile feedback are perceived as a reward, and when paired with a purchasing behavior like adding an item to a cart, can induce increased purchase intent and greater market basket size. These findings have broad implications for the use of vibrational rewards to modify a wide ambit of other mobile consumer behaviors.

**Augmented Reality Helps Low-Involved Consumers Build Self-Brand Connection**

**EXTENDED ABSTRACT**

Augmented reality (AR) bridges physical and virtual worlds by overlaying an image of a product onto the physical world (Javornik 2016). For example, customers use their mobile devices to project how Ray-Ban sunglasses look on their face, or which Cover-Girl lipstick looks good on them without physically trying them on. Since strong visual effects in product presentations help consumers imagine actual product experiences (Vessey and Galletta 1991), we hypothesize that integrating AR into consumers’ shopping experience strengthens consumers’ self-brand connection, especially for low-involved consumers.

How does AR enhance low involved consumers’ connection with brands? We argue that AR-assisted shopping experiences helps them to infer that the brands utilizing AR technology are communal, since AR-based assistance is intended to help fulfill consumers’ needs. Consumers build relationships with brands in much the same way as they form relationships with people (Fournier 1998), and these can be either exchange-based or communal-based relationships (Clark and Mills 1993). Exchange relationships are monetary transaction based, whereas communal relationships are like friendships, where the focus is on caring and satisfying the partner’s needs. For example, consumers who perceive a communal relationship with a brand are likely to perceive that the brand cares about their personal needs (Aggarwal 2004).

Together, we predict that AR increases the perception that a brand is communal, which will then enhance self-brand connection. We expect this effect to ensue particularly among low-involved consumers who use peripheral route processing and rely on environmental cues like AR assistance during their choice of products (Petty and Cacioppo 1986). By contrast, high-involved consumers are more likely to use central route processing and focus on actual product attributes and ad argument quality. Therefore, they are less likely to rely on AR-assisted shopping and the consequent brand image as communal to enhance their connection with the brand.

Study 1 shows that consumers who are low involved in shopping can build strong self-brand connection after using (vs. not using) AR. In a 2 (AR vs. control) × 2 (high vs. low involvement) between-subjects design, 169 participants reported their attitude toward Ray-ban sunglasses twice – before and after negative brand information was given. This is a common measure of self-brand connection (Ahuwalia, Burnkrant, and Unnava, 2000). Our prediction was that participants who have a strong self-brand connection would be less disturbed by the negative information and continue to prefer the brand (i.e., small change in brand attitude due to negative information). We manipulated involvement (Litt and Tornala, 2010) by varying the importance of this shopping task (e.g., High involvement: “Your opinion counts!” vs. Low involvement: “Broad anonymous group’s preferences”). Participants shopped for Ray-ban sunglasses, either by overlaying sunglasses onto their own photo (AR condition) or using a default model’s face (Control condition). Among less involved participants, those who used AR (vs. Non-AR) defended the brand by reporting small change in their attitudes after hearing negative information about the brand (M_{AR} = 0.42 vs. M_{Non-AR} = 1.24; p = .018), whereas AR did not affect highly involved participants’ attitude change. There were no differences in participants’ choice of sunglasses, their product liking, nor their psychological ownership over the chosen product (all n.s.).

Study 2 replicates the findings using Sephora brand. Female participants (N = 181) were randomly assigned to one of the 4 conditions in a 2 (AR: yes vs. no) × (involvement: high vs. low) between-subjects design. We again manipulated involvement by varying the importance of the shopping task. Next, participants either used the AR feature or not to shop for lipsticks.

Participants in the AR condition used their webcam to take a picture of themselves, and applied lipsticks on their face using the AR feature. Participants in the non-AR condition used default model pictures provided from Sephora. Then, we measured self-brand connection using scale from prior literature (Escalas and Bettman 2005). Participants shopped for Ray-ban sunglasses, either by overlaying sunglasses onto their own photo (AR condition) or using a default model’s face (Control condition). Among less involved participants, those who used AR (vs. Non-AR) defended the brand by reporting small change in their attitudes after hearing negative information about the brand (M_{AR} = 5.46 vs. M_{Non-AR} = 4.61; p = .005). There was no significant difference within the high involvement condition. People’s liking of the chosen lip products also did not differ across conditions. We also measured whether AR enhances mental simulation of the process and the outcome of the consumption experiences; however, we did not find significant differences across conditions (all n.s.).

Study 3 demonstrates that AR’s effect on self-brand connection among low involved participants are driven by their inference about brand’s communal characteristics. In a 2 (high vs low involvement) × 2 (AR vs. non-AR) design, we manipulated involvement by again varying the importance of the shopping task. Then, participants shopped for throw pillows from Amazon app using smartphone. Participants in the AR condition used the AR feature in the app, so they could virtually see an image of the throw pillow on an actual chair in the lab. That is, the app overlaid a digital image of a pillow on par-
Participants’ camera view of the chair. Participants in the Non-AR condition shopped for a throw pillow using a typical search procedure on Amazon app. We measured perception on communal relationship with the brand on an 8-item scale (Aggarwal 2004).

Results revealed that among low involved participants, using AR increased their self-brand connection with Amazon (M = 4.65 vs. M_all  4.13; p = .044). There were no differences within the high-involvement condition (n.s.). Supporting our prediction on the process mechanism, we found a significant mediation effect of relative communal score (PROCESS Model 8: CI = [-.34, -.05]). Participants’ liking of the chosen products and positive affect arousal during the shopping task did not differ across conditions.

In summary, our results reveal that consumers who are less involved in shopping infer from AR-assisted shopping experience a communal brand image, which then increases their connection with the brand. In contrast, when consumers are already highly involved in shopping do not rely on such cues and heuristics for their inference, therefore using AR does not increase self-brand connection.

Understanding Consumer’s Product Decisions When Shopping by Voice

EXTENDED ABSTRACT

Despite the rapidly evolving of artificial intelligence and the technology infusion in retailing, sparse research exists on this topic in marketing literature (Grewal, Roggeveen and Nordfält 2017). Compared with traditional online shopping that navigated by point and click (i.e., click-based interaction), shopping with virtual assistant allows consumers to place an order either by talking (i.e., voice-based interaction) or texting message (i.e., text-based interaction). Based on previous research, which suggests that expression modality can influence consumer’s decision making (e.g., Kless, Levav and Goukens 2015; Shen and Sengupta 2018), we propose that voice-based interaction will make consumers more likely to choose the recommended product during their online shopping journey.

Prior research shows that people’s attitude towards an object can be determined by how they interact with it. For example, socially interact with a robot can increase the anthropomorphism of the robot (e.g., Peca et al. 2015). We propose that since voice-based interaction carries more social functions than text-based interaction or click-based interaction (e.g., Chafe 1982), engaging in voice-based interaction will incite people to feel that they’re interacting with a social actor rather than a computer. Consequently, this enhanced social perception will lead to compliance behavior (Cialdini 2016).

As a result, consumers will end up purchasing more recommended products. Furthermore, we also argue the interaction effect may only exists in dialogical interaction, where people will get social responses from the computer reciprocally but will diminish in monological interaction, where the computer’s social responses are absent. This is because social interaction is two-way in nature, while one-way communication will create social distance and undermine the social bonds between communicators (Andreoni and Rao 2011).

A fictitious online food ordering website was developed to examine our hypotheses. The website contains three product categories: pizza, sandwiches and chicken wings. Under each category, five to six products are provided, and some are labeled as recommended (i.e., regular recommended products). Before checkout, participants will be asked whether they would like to add a salad or fries to their orders (i.e., add-on products). The measurement of recommended products includes both regular recommended products and add-on products. We also created different website versions to manipulate both user communication modality (speak vs. click vs. type) and computer’s response modality (social response vs. non-social response). To simulate computer’s social response, we let the website communicate to participants in either synthesized voice or interactive text. Meanwhile, in the non-social condition, we used static text on the website and also made the content less interpersonal.

Five studies have been conducted with responses from more than 3,000 MTurk workers. In all the studies, participants were asked to complete an online shopping task on the given website. Study 1 demonstrates the main effect. It also examines the role of controllability (i.e., whether the communication can be interrupted). Participants were randomly assigned to either shopping by voice (incorporating synthesized speech), click-interruptible or click-non-interruptible (incorporating pop-up text) condition. Consistent with our hypotheses, when shopping by voice, participants purchased more quantity of recommended products (p < .01) and also more add-on products (p < .01). No differences were found between the two click conditions (ps > .60), suggesting controllability doesn’t influence product decisions.

Study 2 examines the effects of both user communication modality (speak vs. click) and computer’s response modality (synthesized speech vs. interactive text). We also included a plain website without any extra website information as baseline. The results revealed that speak modality leads to more recommended products (p < .01), and more add-on products purchased (p < .01). We also investigated the possible influences of computer response modality and controllability individually, however, the results didn’t reveal any significant differences on the major measurements (ps > .28).

Study 3 compares voice-based interaction with both click-based interaction and text-based interaction. Consistent with the last two studies, in the voice-based interaction, participants purchased more recommended products (p < .01) and more add-on recommended products (p < .01). Again, no significant differences were found between synthesized voice and interactive text conditions on the major dependent measurements (ps > .15).

Study 4 employs a 3 (user’s communication modality: speak vs. type vs. click) by 3 (computer’s response modality: synthesized voice vs. interactive text vs. non-social information) between subject design and investigates both user’s communication modality and the moderating role of computer’s response modality. We found that using speak modality leads to more recommended products purchased only when computer responds in synthesized voice (p < .01) or in interactive text (p < .01), but not in the monological condition without computer’s social responses (p = .65). Similar pattern was also observed for the add-on product purchases.

Study 5 provides further support to the interaction effect between user’s communication modality and computer’s response modality. In addition, it also examines the proposed mediating role of perceived socialness (Wang et al. 2007). Specifically, using speak modality leads to more recommended products purchased only when computer respond in synthesized voice (p < .1) or in interactive text (p < .01), but not in the monological condition where computer’s social responses are missing (p = .16). To test the mediation, with user’s interaction modality type as the independent variable, computer’s response modality as the moderator, perceived socialness as the mediator, and the number of recommended products purchased as the dependent variable, the 95% bias-corrected bootstrap confidence interval, obtained using 10,000 bootstrap samples, did not include zero, indicating a significant indirect effect of perceived socialness on choosing of recommended product.

In sum, this research shows that when shopping by voice, consumers are more likely to choose recommended products, and this effect is driven by perceived socialness. This work contributes to
existing communication and human-computer interaction literature and also provides important managerial implications to practitioners for designing a more effective virtual assistant system.

How Do Consumers Value their Private Data?

Chairs: Geoffrey Tomaino, INSEAD, Singapore
Klaus Wertenbroch, INSEAD, Singapore
Daniel Walters, INSEAD, France

SESSION OVERVIEW
With the advent of objective and measurable tracking of online behaviors came a recognition that such data could be used for consumer segmentation and targeting. While such microtargeting reduces search frictions and allows for more relevant advertising, it comes at a cost of consumers’ privacy. How do consumers conceive of this loss of privacy in the face of efficiency gains from technology? This session asks how consumers navigate this landscape. Within this broader line of questioning, a central element running through the papers in this session is the nature of context and how it impacts consumer attitudes/behaviors towards their private data. Three of these papers experimentally demonstrate the impact of situational factors on a consumer’s sense of privacy, while Brough and Martin, a conceptual paper, argue that privacy should be recognized as a mindset.

Overall, these papers call attention to the idea that consumers are still learning how to assess an online experience that is increasingly surveillant and how to manage their private data in line with their goals.

In contrast to contexts where privacy concerns are already salient, in this research we examine conditions under which privacy concerns may be dormant and, in this context, challenge the assumption that privacy notices increase a consumer’s sense of security. Instead, we argue that privacy notices, although designed to promote a sense of confidence that personal data will not be misused, can decrease perceived security and purchase intent (relative to a condition in which privacy assurances are either not provided or less salient).

We refer to this finding as the bulletproof glass effect because a privacy notice may be analogous to bulletproof glass; although designed for protection, its very presence may raise the salience of potential dangers and paradoxically cause consumers to feel more vulnerable than they would in its absence (holding constant the actual level of risk in the environment). We attribute this ironic consequence to the heightened risk awareness we expect them to produce.

Evidence from a field experiment and five lab studies is consistent with these predictions and lends support to our proposition that the mere presence of a privacy assurance can undermine rather than enhance perceived security and purchase intent.

Paper #4: From Privacy Concern to Privacy Mindsets
Aaron R. Brough, Utah State University, USA
Kelly D. Martin, Colorado State University, USA

EXTENDED ABSTRACT
Consumers regularly encounter privacy policies explaining if and how their personal information will be collected, stored, used, and shared. Most consumers desire such assurances; in a pilot test, only 14.3% of respondents indicated that they would rather do business with a company that does not have a privacy policy than with one that does.

To consumers with salient privacy concerns, the assurance offered by a privacy notice might be appealing for several reasons. First, privacy notices place legally-enforceable limits on how organizations can collect, store, use, and share consumers’ personal data. Second, privacy notices often communicate security measures (e.g., encryption, firewalls) that are in place to protect consumer information from misuse. Third, in locations and industries where privacy notices are not mandated by law, the fact that a company voluntarily opts to disclose its data practices may signal that it is forthcoming and trustworthy.

Brough et al. demonstrate that consumer conceptualizations of privacy are indeed more nuanced than might be intuited. Specifically, they demonstrate that assuring consumers that their data is secure can actually increase vigilance and thus negatively impact purchase intent, a phenomenon the authors refer to as the “Bulletproof Glass Effect.”

Tomaino et al. further demonstrates the importance contextual information on how individuals evaluate their privacy, specifically by examining how consumers handle this newly marketable resource. The paper demonstrates that individuals value their privacy less when exchanging it for goods than when they exchange the same amount of their private data for money. The findings cast doubt on the efficiency of the ever-growing market for personal data.

Brough and Martin provide a framework that aids in understanding the complex nature of private data ownership and transactions highlighted in the aforementioned papers. Specifically, this is done through drawing attention to “privacy mindsets” or malleable psychological states that characterize how we conceptualize privacy.

Together, these papers raise a line of questioning related to the protection of our private data that goes beyond just an impulse to do so. By investigating the impact of contextual factors on consumer decision making in the realm of private data, we can better understand and aid consumers as they progress towards their goal of responsibly managing and protecting their data while still gaining benefits from the exchange thereof.

The Bulletproof Glass Effect: When Privacy Notices Backfire

Advances in Consumer Research
Volume 47, ©2019
Study 1 was a field study among more than 15,000 prospective customers of a financial services firm, demonstrating the bulletproof glass effect by showing that increasing the salience of a privacy notice reduced enrollment rates.

Study 2 provided a conceptual replication of the bulletproof glass effect in the lab, showing that the presence (vs. absence) of a privacy notice can ironically decrease rather than increase purchase intent (and that this effect is mediated by a decrease in perceived security).

Study 3 showed that despite the opposite outcomes they are designed to produce, both assurances and warnings can decrease consumer interest in a product. Purchase interest and perceived security were lower not only after receiving a warning prime, but also when a privacy policy was present (vs. absent).

Study 4 showed that the bulletproof glass effect influences downstream consequences, such that the presence versus absence of privacy notices changes consumers’ personal willingness to pay for a product (without affecting their perception of the product’s value in the marketplace). As predicted, although the presence of a privacy policy decreased willingness to pay, it did not decrease expected retail value.

Study 5 provided additional support for our theory that the salience of privacy concerns drives the bulletproof glass effect by showing that the effect is a function of the evaluation context, such that it is more likely to be observed in separate rather than joint evaluation (where privacy concerns are made salient by comparative processing). Consistent with our predictions, the bulletproof glass effect observed in our previous studies was replicated in separate evaluation, but attenuated in joint evaluation.

Finally, study 6 used a very conservative test in which mere awareness that a privacy policy exists, even when its content is not seen, was sufficient to decrease purchase intent and affect a behavioral measure of willingness to disclose personal information.

From a theoretical standpoint, this research highlights conditions under which consumers process assurances as warnings and provide new insights regarding persuasion and the drivers of perceptions under which consumers process assurances as warnings and behavioral measure of willingness to disclose personal information.

These findings parallel prior research suggesting that contrary to their overt intentions, warnings can be reassuring. For example, consumers seem to trust advisors who disclose conflicts of interest (Cain, Loewenstein, and Moore 2010) and tend to be more persuaded by messages that include negative information (Ein-Gar, Shiv, and Tormala 2012; Herr, Kardes, and Kim 1991; Ward and Brenner 2006). We complement such research by showing that likewise, contrary to their overt intentions, assurances can be disconcerting—particularly in contexts in which initial risk awareness is low.

Moreover, our findings bolster the paradoxical phenomenon that although most consumers claim to want transparency in privacy practices, they may react negatively to it—greater transparency in the form of privacy policies can sometimes backfire and reduce rather than enhance perceived security.

Our findings that mere awareness of the existence of a privacy policy—even when it is not viewed—can decrease interest in purchasing a product, suggest that companies have an incentive not to provide privacy notices (despite demands by consumer advocacy groups for greater transparency in how private consumer data is managed). This negative incentive may hinder compliance, and even if regulators enforce compliance it could lead to a climate of distrust as consumers’ perceptions of security are decreased rather than increased by the additional assurances. However, we also show that in joint evaluation, the bulletproof glass effect is attenuated, suggesting that companies wishing to provide assurances without detracting from consumers’ perceptions of security may increase their chances of success through direct comparison to a competitor that is less transparent in its data practices.

**Telling Your Secrets to an AI: Consumers Prefer Disclosing Private Personal Information to an AI (vs. a human)**

**EXTENDED ABSTRACT**

In the new data-driven economy, it has become standard practice for consumers to be asked to share increasingly personal information about their consumption experiences and preferences. Several scholars have noted that this trend poses new privacy hazards for consumers (e.g., Phelps, Nowak, & Ferrell, 2000). The addition of artificial intelligence (AI) has made the picture more complex as AI collect and process huge amounts of data, making it possible to aggregate and profile consumer information to predict behaviors and attitudes that consumers may not be comfortable disclosing. In this sense, AI may pose an even bigger threat to privacy. However, ironically, our research shows that consumers may be more likely to disclose private information to a corporate AI than a human corporate employee. Past research demonstrated that privacy decisions are highly malleable: consumers are less defensive to privacy violations in less physical and sensorial environments, such as online as opposed to face to face interactions (Acquisti, Brandimarte, & Hancock, 2015). Because AI is often perceived as a disembodied computer program (Dietvorst, Simmons, & Massey, 2015), we theorize that consumers are often more likely to reveal their personal information to an AI (vs. a human). We theorize that these differences are driven by greater concern of the potential future uses of data by AI versus human analysts. We further theorize that this effect is enhanced when the content of the information casts the self in a negative light, such as when disclosing embarrassing or guilt-inducing experiences. We show that no such disclosure effect exists when sharing general negative emotional experiences with no negative implication for the self (e.g., sad experiences).

In Study 1, 288 participants recruited from MTurk and were asked about their past experiences purchasing condoms. After completing a brief questionnaire of their past experiences, we asked participants to indicate to what extent they were willing to disclose the following personal information (1 = absolutely no; 9 = absolutely yes): phone number, home address, a selfie, a photo of their family, their internet browsing history. In the AI (human) condition, we told participants that the information collected would be processed by a computer algorithm (a human analyst). We found that participants were more likely to disclose personal information to a computer algorithm (M = 2.06) than to a human (M = 1.59), F(1, 286) = 7.10, p < .001.

In Study 2, fifty-nine undergraduate students participated in the study and were randomly assigned to one of the conditions in a 2 (agent: AI Alexa, human confederate) between-subjects design. Participants were told that they would write one of their consumption experiences that made them feel guilty and the purpose of sharing the experience was to learn about their personal preferences and make them personalized product recommendations. In the AI Alexa (human) condition, Amazon’s voice assistant Echo (a human confederate) was made visible to the participants and they were told that their written texts will be assessed by Alexa (by the person).
After the completion of the guilt writing task, participants reviewed their own writings and reported the extent to which their writings disclose “personal information” and “private information.” (1 = not at all, 7 = very much). The two items were averaged to create a privacy disclosure index (α = .89). As predicted participants in the AI condition (M = 4.66, SD = 1.43) felt that they had disclosed more private information compared to the human condition (M = 3.77, SD = 1.45), F(1, 57) = 5.63, p = .021. Further, a judge who was blind to the experimental design coded the the extent to which the writing disclosed private and personal information (1 = not at all, 5 = very much). Consistent with participants’ self-report, the judge’s coding revealed that participants in the AI condition (M = 2.97, SD = .91) disclosed more private information compared to the human condition (M = 2.53, SD = .73), F(1, 57) = 4.09, p = .048.

To demonstrate privacy concern is the underpinning reason, we suggest that this above effect only holds for disclosure of private information (e.g., an embarrassing or guilty experience), but not for disclosure of non-private information (e.g., a sad experience). Thus, in Study 3, one hundred and sixty participants from MTurk were randomly assigned to one of conditions in a 2 (agent: AI, human) x 2 (emotion: guilt, sadness). Participants in the AI (human) condition were told that their writing would be reviewed by an “AI” (“a human”). Then participants were instructed to describe one of their experiences that made them feel either guilty or sad. Just as in Study 2, participants wrote about the experience and reported the extent to which their writing disclosed “personal information” and “private information.” (1 = not at all, 7 = very much). The two items were averaged to create the index of disclosure (α = .91). The index was submitted to a 2 (agent: AI, human) x 2 (emotion: guilt, sadness) ANOVA. The result revealed only a significant interaction between agent and emotion, F(1,156) = 13.45, p < .001. Also, pairwise comparison showed that when participants described their guilty experiences, they disclosed more private information to an AI (M = 2.42, SD = .84) than to a human (M = 1.90, SD = .42), F(1,156) = 15.14, p < .001. There was no difference in disclosure of sad experiences between the two types of agents, p = .186.

In summary, this research shows that individuals are more likely to reveal their private information to intelligent non-human agents (vs. human agent) and paradoxically, to view this information as being more personal. We posit that these effects are driven by greater concerns over future usage of personal information by AI as compared to humans. We further show that this effect only pertains to information that casts the self in a negative light, such as guilt-laden or embarrassing experiences. Our findings suggest that firms should decrease (increase) human (AI) involvement when the consumption context is likely to trigger negative social emotions.

Consumers Place a Lower Value on Private Data When Exchanged for Goods as Opposed to Money

EXTENDED ABSTRACT

The acquisition and use of consumer data is central to the business models of most consumer-facing firms. Private data is a resource, one for which consumers should demand a consistent and equitable payment. For instance, users provide websites with their private data in return for services offered by these sites (e.g., access to social networks). This suggests that users ought to value the services offered by these sites more than the private data they provide. However, our results show that this is not necessarily the case. That is, when exchanging private data for a good as opposed to exchanging the same private data for money, consumer preferences for privacy are intransitive, violating a basic axiom of rational choice theory (von Neumann and Morgenstern 1944). More specifically, we show that consumers demand less value in goods/services than they do in money when “selling” their private data. By demonstrating this systematic violation of rationality when valuing private data, our research also provides further suggestive evidence that markets for private data are inefficient (Acquisti et al. 2013).

We propose that consumers undervalue their private data when trading them against goods/services, relative to money, because they do not view their data as a marketable resource, even though they are to firms. Consider a consumer using the services of Uber. Whereas the consumer conceives of this as a simple monetary transaction of a fare for transportation, Uber also collects personal data and uses this information to generate profits. We propose that the consumer neglects to fully incorporate the value of their data in this exchange. Consider a second scenario where the same customer is asked to sell this same data in a purely monetary transaction. We propose that the sale price of data will be higher in this monetary transaction compared to the exchange of data for value in the form of goods. We suggest that the difference in valuations occurs because a monetary transaction conveys to consumers that private data are a marketable resource in a way that an exchange setting does not. Given that the loss associated with giving up private data is identical in both settings, making consumers aware of this information ought to increase their valuations in a monetary transaction setting.

In Study 1, we tested our central hypothesis in an incentive-compatible setting. Participants were recruited through Prolific Academic (N=140, pre-registered on aspredicted.org). Participants entered the experiment and completed three blocks of a price list tradeoff task: In the first block, participants indicated the amount of money they would demand to give up three hours of their GPS data. In the second block, participants indicated how much of a good/service (either Amazon movie downloads, Starbucks medium beverages, etc.) they would demand to give up the same three hours of GPS data. In the final block participants indicated the monetary amount at which they valued the good/service determined in block 2. The order of the blocks was randomized and the good/service chosen was determined in a pre-survey based on which good/service participants would most like to receive. Participants were also told that in 100 people would be drawn to have an actual choice made in the experiment enacted. We found that participants valued three hours of their GPS data at a lower rate (£36.77) when exchanging the data for goods/services than when exchanging them for money (£45.12).

Study 2 was a pre-registered replication of Study 1 with a larger sample size (N=301) and lower incentives (such that participants faced a 1 in 300 chance of being drawn to have one of their choices enacted). Despite these lower incentives, the results were substantively identical, suggesting that our findings are not sensitive to the experimental incentive structure.

The purpose of Study 3 (N=603, pre-registered on aspredicted.org) was to examine our proposed mechanism for the results of Studies 1 and 2. Namely, we hypothesized that these results were driven by individuals’ inexperience in valuing their private information. To test this, we recruited a participant sample from Amazon MTurk and implemented the same design as Study 1 but added a between-subjects element, in which participants considered the relevant tradeoffs either with giving up three hours of their GPS data (privacy condition) or the performance of a three-hour MTurk image coding task in mind (labor condition). We chose the latter because we expected MTurk participants to be well-practiced in valuing their labor on the site, which should diminish the intransitivity relative to that hypothesized in the privacy condition. In the privacy condition, participants valued their private data higher (M=$57.89) when
exchanging them for money than when exchanging them for goods/services (M=$48.15), whereas there was no such difference in the labor condition (M=$46.09 versus M=$45.24).

In summary, this research provides evidence that individuals exhibit systematic errors when attempting to value their privacy. This also suggests that inefficiencies may be common in the ever-growing market for personal data.

**From Privacy Concern to Privacy Mindsets**

**EXTENDED ABSTRACT**

Foundational to extant privacy research is the notion of privacy concern, which describes apprehension about the potential acquisition and use of one’s personal information. As the measurement of privacy concern has evolved, different typologies have been developed.

Some privacy typologies classify individuals by the degree of privacy concern they exhibit. For example, according to a popular "Privacy Segmentation Index" developed as part of a series of ongoing privacy surveys by Alan Westin, individuals are classified into one of three segments: fundamentalists, who consistently exhibit high privacy concern; unconcerned, who consistently exhibit low privacy concern; and pragmatists, who exhibit inconsistent levels of privacy concern (Kumaraguru and Cranor 2005).

Other typologies classify information (rather than people) by the degree of privacy concern it elicits. For example, one study classifies information (e.g., height, cell phone number, salary history, and credit card number) into four categories ranging from public information to highly sensitive information (Tsai, Cranor, Acquisti, and Fong 2006).

Inherently implied in typologies is an assumption that individuals and information can be reliably categorized by stable traits. However, researchers have begun to question this assumption. For example, contextual integrity theory rejects the notion that individuals uniformly perceive certain types of information to be inherently more sensitive (Martin and Nissenbaum 2016), asserting instead that perceptions are context-dependent (Nissenbaum 2019). To illustrate, one may be willing to provide certain information in an app that they would not provide online. Similarly, a cell phone number may be considered sensitive in one context but not another.

By acknowledging the malleability of privacy perceptions, such research constitutes a meaningful advance beyond static typologies. Yet, privacy concern remains the focal construct of interest (Martin and Murphy 2017). Privacy concern originated as a way to consistently measure privacy, but has evolved to become a de facto conceptualization of privacy. This is problematic because privacy concern is limited in scope and does not represent the full breadth of privacy attitudes. It reflects a negatively-valenced, future-oriented, and reasoned attitude about the possible exposure of personal information, but fails to capture privacy-related attitudes which are positively-valenced, present-oriented, and heuristic in nature. Its measurement is often narrowly focused on reactions to information disclosure requests, neglecting other situations in which privacy is important and relevant (e.g., surveillance, digital tracking).

In response to these challenges and limitations, we propose that a more robust conceptualization of privacy is needed—one that acknowledges context-dependence and is broadly-applicable to all privacy situations.

**Privacy Mindsets**

We introduce privacy mindsets as a way to incorporate additional relevant dimensions of privacy and better understand the context-dependent interaction of individual and situational characteristics that shape attitudes towards the exposure of personal information. Specifically, privacy mindsets describe attitudes, beliefs, and knowledge structures concerning the self-initiated or other-initiated exposure or concealment of an individual’s personal information and actions.

In general, mindsets are chronic or situationally-activated psychological orientations that, when accessible, affect the selection, encoding, and retrieval of information and drive evaluations, actions, and responses (Rucker and Galinsky 2016). Like other mindsets, the adoption of a privacy mindset can be chronic or situationally-activated, and may spill over to subsequent, unrelated tasks (Ülkümen, Chakravarti, and Morwitz 2010).

Privacy mindsets reflect three distinct psychological orientations that describe the interaction between individuals’ sense of personal exposure and their sensitivity to changes in the objective level of personal exposure.

**Vigilant:** Irrespective of the objective level of personal exposure, adoption of a vigilant mindset results in a feeling of exposure and a belief of being monitored. Thus, in a sheltered environment, a vigilant mindset creates the illusion of surveillance, leading to impression management as one adjusts actions and curates information for an imagined observer. If having one’s actions monitored or personal information accessed is undesirable, a sense of paranoia may be experienced. On the other hand, if a sense of being monitored or sharing personal information is regarded as positive, individuals may seek opportunities to perform for or share with an audience—real or imagined. Whether exposure is perceived as positive or negative, a vigilant mindset supersedes environmental conditions in determining one’s behavior.

**Relaxed:** Irrespective of the objective level of personal exposure, adoption of a relaxed mindset results in feeling agnostic towards exposure. Regardless of whether personal data is sheltered or exposed, individuals with a relaxed mindset are not attuned to whether, how, and when their personal actions are being monitored and their information collected, accessed, and used. Like an innocent child who is ignorantly unaware of its vulnerability, individuals with a relaxed mindset may simply be naïve about the exposure of their personal information. Alternatively, they may be aware of exposure but lack the empowerment or motivation to change it.

**Responsive:** This orientation describes a state of mind in which individuals are sensitive to differences in the level of objective exposure and regulate their behavior accordingly. In an exposed environment, individuals who adopt a responsive mindset seek to protect personal information if sharing is regarded as negative, and seek to reveal personal information if sharing is regarded as positive. In a sheltered environment, a responsive mindset leads people to be more open and less guarded than in an exposed environment.

In contrast to typologies that attempt to classify individuals into a single segment, privacy mindsets are fluid states of mind that can be situationally-activated, such that the same individual may shift repeatedly between mindsets in different contexts. Of course, privacy mindsets may also be chronically adopted, such that one is predominant across most contexts.

Our conceptualization of privacy as a mindset answers previous calls for an expansion of the narrow focus on privacy concern that has dominated privacy research (Smith, Dinev, and Xu 2011). Incorporating psychological and environmental factors, privacy mindsets encompass the present as well as the future, account for positively-and negatively-valenced thoughts, and consider heuristic as well as reasoned judgments.

SESSION OVERVIEW
Recent years have witnessed a rapid expansion in the types of technologies that consumers use to browse, consume, make decisions, and communicate. As an example, 77% of the adult population in the United States now owns a smartphone (Pew Research Center 2018), with the device being used not just for communication but also to perform almost all online activities. In addition, more than 20 billion smart objects, such as Amazon Echo devices, are connected to the Internet (Howell 2017). These technological devices have even become increasingly interconnected, with consumers using smartphones to operate their smart technologies and automate behaviors and decisions they used to make themselves. The consequences for practitioners have been no less dramatic: whereas firms were once mostly confined to in-person interactions with customers, these communications are now increasingly conducted through a constellation of textual, visual, and other virtual media.

The goal of this special session is to shed light on a burgeoning field of research on the psychological consequences of consumers’ engagement with new technologies. The session will be comprised of four papers that explore two central questions in this area:

1. How might new technologies be changing consumer behavior and decision-making?
2. Under which conditions, and to what extent, are new technologies enhancing or harming consumer well-being?

The first two papers in this session explore this first question. Melanie Brucks and Jonathan Levav explore how video-conferencing affects collaboration processes in new product development. They find that while video conferencing curtails the number of new ideas generated, it facilitates identification of the best idea. Next, Shiri Melumad and Robert Meyer investigate how consumers’ increased reliance on their smartphone may be affecting user-generated content in a way that has important policy implications. The authors find that consumers tend to disclose information that is more sensitive or personal when generating content on their smartphone versus PC.

The third and fourth papers then explore the second key question of the session, with a particular focus on the relationship between new technologies and humanization. Christian Hildebrand, Donna Hoffman, and Tom Novak examine how the constricted nature of verbal communication that typically marks consumers’ interactions with IoT devices (e.g., Amazon Alexa) acts to dehumanize such interactions, reducing consumers’ overall satisfaction with IoT experiences. Finally, the session concludes with work by Juliana Schroeder, who explores a different aspect of humanization: that which arises when consumers engage in conflict via text or in person. She finds that while consumers turn to text-based communication in the belief that it will deflate conflict with an ideological opponent, such interaction instead acts to dehumanize conversants and thus inflate the degree of conflict.

We believe that this session will contribute to the conference by showcasing research on human-technology interactions, an increasingly important topic that spans disciplines such as psychology, sociology, anthropology, and computer science. We hope that consumer researchers will play a major role in this field as it continues to develop, and that this session will illustrate the potential research opportunities in this area.

Technology-Mediated Innovation
EXTENDED ABSTRACT
The move to virtual teams is one of the most notable business trends of the last decade. 43% of people today work remotely (Gallup 2017), and 65% of firms now use distributed teams (Upwork 2018). Underlying this shift to remote work are new technological advances that enable virtual collaboration, such as video-conferencing. The implicit presumption is that these technologies can replace face-to-face interaction. In the present research, we test this assumption for one of the most important collaboration processes in marketing: creating new products, where teams brainstorm nascent ideas and then select ideas to develop into proposals and/or prototypes. Importantly, these two tasks correspond to different psychological processes: while idea generation leverages expansive, unregulated thinking (Nijstad and Stroebe 2006), idea evaluation and selection benefits from analytical and deliberative thinking (Amer, Campbell, and Hasher 2016).

Does communicating in-person meaningfully differ from video-conferencing for these two processes of new product development? At first blush, it seems like the effect of communication modality should be quite trivial. Indeed, contingent on good internet connection and high-resolution display, video-conferencing closely mimics in-person conversation: it is synchronous (unlike email) and reveals almost identical visual and audio information about the partner (unlike phone calls). However, we propose that an important difference lies in the shared environment: In-person teams share the entire room while, over video, teams only share the screen in front of them. Consequently, virtual teams should primarily look at the video screen, as the majority of the room is not accessible to their partner. When virtual teams concentrate on the screen and filter out peripheral visual stimuli, their visual attention is narrowed (Wade and Tatler 2005). Drawing on research suggesting that cognitive states are sticky (Luchins 1942) and are often recruited for other tasks once activated (Malkoc, Zauber, and Bettman 2010; Moreau and Engeset 2015), we posit that this narrow visual focus spills over into the new product development tasks and activates cognitive focus. Importantly, the focused cognitive state among virtual groups should suppress...
the expansive thinking needed for idea generation but conversely bolster the analytical thinking used in idea selection.

We conducted two lab studies and one field experiment to test this hypothesis. In the first lab study, 150 dyads generated creative uses for a frisbee for five minutes and then selected their most creative idea for one minute. These tasks were incentive-compatible: each creative idea earned one raffle ticket for a $200 raffle and selecting the most creative idea (as scored by outside judges) earned five raffle tickets. Teams were randomly assigned to work together for these tasks either in-person or virtually (with their partner displayed via video across from them). Virtual teams generated significantly fewer creative ideas ($M = 6.17$) than in-person teams ($M = 7.36$, $p = .005$), but selected ideas that were more creative ($M_{\text{virtual}} = 4.71$, $M_{\text{in-person}} = 4.50$, $p = .043$, controlling for the creativity of the top idea).

We hypothesized that virtual communication affects new product development because the constrained environment of the screen fosters a focused cognitive state. In a second lab study, we explored the proposed mechanism by having 150 dyads generate uses for bubble wrap either in-person or virtually in a room populated with props. We captured environmental focus in two ways. First, participants recalled the props in the room, and second, we recorded and extracted participants’ eye gaze throughout the task. If teams are more environmentally focused on the screen in the virtual condition, they should recall fewer objects in the room and their gaze should be more oriented towards their partner (the screen). Virtual teams again generated significantly fewer creative ideas ($M = 7.55$) than in-person teams ($M = 8.62$, $p = .020$), but selected a more creative idea overall ($M_{\text{virtual}} = 3.93$, $M_{\text{in-person}} = 3.72$, $p = .081$, controlling for the creativity of the top idea). Moreover, we found evidence that indeed the environmental focus was more constrained in the virtual condition. Virtual teams remembered significantly fewer props in the room ($M = 3.88$) than in-person teams ($M = 4.77$, $p = .009$), and virtual teams looked significantly more at their partner ($M_{\text{virtual}} = 102.90$ seconds, $M_{\text{in-person}} = 65.10$ seconds, $p < .001$) and less at the surrounding room ($M_{\text{virtual}} = 8.32$ seconds, $M_{\text{in-person}} = 26.11$ seconds, $p < .001$). Importantly, gaze mediated the effect of communication modality on idea generation (95% CIs: [-1.29, -.12]).

The lab results suggest that merely being in the same room as your partner (vs. communicating virtually) changes how the processes of idea generation and selection unfold. However, in order to make recommendations to firms, we wanted to test these effects in the field with domain experts who are invested in the outcome, know their partners, and regularly use the virtual technology in distributed teams. To do this, we ran an ideation workshop where 308 Nokia engineers generated ideas for an hour and then selected and developed one idea for 45 minutes either in person or over video-conferencing. At the end of the workshop, the teams submitted their developed proposals, and experts within Nokia evaluated the submissions. Because the experts only evaluated the submitted idea, to capture selection accuracy, we instructed teams to evaluate their own idea after it was submitted using the same criteria the company experts used. Teams who are more accurate in their evaluation should better match the experts. Replicating the lab, we find that engineers who worked together virtually ($M = 7.88$) generated fewer ideas than in person ($M = 9.10$, $p = .009$). In addition, we find that there is a smaller difference between the teams’ self-evaluation and the experts’ evaluation (thus the evaluation was more accurate) among virtual teams ($diff_{\text{virtual}} = .99$, $diff_{\text{in-person}} = 1.25$, $p = .039$).

We are facing unprecedented levels of virtual communication among consumers and within firms. While seemingly interchangeable with face-to-face interaction, our studies suggest that these communication technologies have important psychological consequences: virtual interaction may undercut the value of collaborative brainstorming but can be leveraged for evaluation and development.

**Full Disclosure: How Smartphones Enhance Consumer Self-Disclosure**

The past fifteen years have witnessed two transformative trends in consumer markets: firms’ reliance on user-generated content as a means of gaining insights into consumer preferences, and the emergence of the smartphone—rather than personal computer—as the primary platform on which this content is generated. In this research we explore a question that lies at the intersection of these two trends: might the transition away from PCs toward smartphones be altering what consumers reveal about themselves online? Using data from thousands of customer-generated online posts, as well as two controlled experiments, we offer evidence that it indeed might, and in a way that has important implications for both firms and policymakers. We show that consumers tend to exhibit greater depth of disclosure when writing on their smartphone (vs. PC).

In particular, we propose that writing on one’s smartphone often lowers the barriers to revealing certain types of sensitive information due both to its unique form characteristics as well as the emotional associations consumers tend to hold with their device. The first pathway draws on social presence theory (e.g., Scheier and Carver 1983), arguing that its smaller screen (vs. PC) more narrowly focuses consumers’ attention on the disclosure at hand and away from their external environment, something that fosters greater private self-awareness. This heightened private self-awareness, in turn, enhances consumers’ depth of disclosure on the device (e.g., Derlega, et al. 1993 Johnson 2001). The second pathway posits that consumers tend to associate their smartphones with more positive, intimate activities (e.g., texting with friends, entertaining themselves), which—combined with the fact that the device is virtually always with them—leads smartphones to represent a general source of psychological comfort for many consumers, which further drives depth of disclosure on the device (e.g., Chaiken et al. 1976; Forgas 2011).

We test the main hypothesized effect as well as its underlying mechanisms across four studies. In the first two field studies we tested for differences in depth of self-disclosure across devices by drawing on a corpus of 369,161 Tweets referencing different “trending hashtags” (Study 1), and 61,643 restaurant reviews posted on TripAdvisor.com (Study 2). Depth of disclosure was measured using both automated natural-language processing tools and human judges. For the automated analysis we measured the relative presence of linguistic markers that had been found in previous research to be associated with greater self-disclosure, including use of first-person pronouns, references to family and friends, and more authentic writing styles (e.g., Davis and Brock 1975; Houghton and Joinson 2012). To collect human judgments we recruited MTurk participants to judge the depth of disclosure (measured as the index of four items on a seven-point scale) in a subset of 4,485 Tweets (Study 1) and 10,185 restaurant reviews (Study 2).

The results confirmed that consumers generated content that was more self-disclosing on their smartphones than on their PCs. For example, across seven topical domains (e.g., news, entertainment), Tweets were more likely to have been written on a smartphone if they were written in a more disclosing, authentic style ($M_{\text{smartphone}} = 28.73$ vs. $M_{\text{PC}} = 21.49$; $F(1, 369148) = 235.30$, $p < .001$), and were perceived by human judges as more self-disclosing ($M_{\text{smartphone}} = 3.25$ vs. $M_{\text{PC}} = 3.07$; $F(1, 7821) = 41.32$, $p < .001$). These results were conceptually replicated in the substantively different domain of TripAdvisor.
where restaurant reviews written by customers on their smartphones were not only more disclosing based on automated measures and human judgments, but were also viewed as more persuasive by outside readers (M_{Smartphone}=4.97 vs. M_{PC}=4.78; F(1, 9861)=36.62, p<.001).

The next two experimental studies tested the hypothesized mechanism underlying the effect: that engagement with one’s smartphone (vs. PC) focuses users more on the disclosure and, in turn, heightens private self-awareness, and also elicits greater feelings of psychological comfort. In Study 3, 714 members of a Qualtrics panel were randomly assigned to use their smartphone or their PC to write about an upsetting personal experience. After completing this, participants were asked to use the same device to respond to a series of questions measuring the proposed drivers of the effect: degree of focus on the disclosure task, private self-awareness, and psychological comfort.

Consistent with the prior results, descriptions written by participants on their smartphones were rated by MTurk judges as displaying greater depth of disclosure than those written on PCs (M_{Smartphone}=4.51 vs. M_{PC}=4.17; F(1, 3401)=16.97, p<.001). Critically, a mediation analysis confirmed a significant positive effect of smartphone (vs. PC) use on degree of focus (b_{Device→Focus}=.05; t=2.35, p<.001), a significant positive path from focus to private self-awareness (b_{Focus→PrivateSelfAwareness}=.24; t=2.29, p<.001), and a significant positive path from private self-awareness to depth of disclosure (b_{PrivateSelfAwareness→DepthOfDisclosure}=.05; t=2.37, p<.001). Likewise, the analysis supported the parallel positive path from smartphone (vs. PC) to psychological comfort (b_{Device→Comfort}=.05; t=2.06, p<.001), and a positive path from comfort to depth of disclosure (standardized b_{Comfort→DepthOfDisclosure}=.09; t=3.78, p<.001). Finally, the results showed a significant total indirect effect of smartphone (vs. PC) use on depth of disclosure through the parallel paths of focus, private self-awareness, and psychological comfort (total indirect effect: b=.01; t=2.81, p=.008).

In the final experiment we replicate these findings among a different form of consumer disclosure. Mirroring the procedure of Study 3, 1,389 Qualtrics participants were again randomly assigned to complete the study on their smartphone or PC and this time were required to state a set of eleven commands that required them to engage directly and need corresponding sensor invoking permissions. This paper presents a novel approach (GVS-Attack, or general user acceptance (Portet et al. 2013)) this calls for technological solutions that suit their specific needs and capabilities. The SWEET-HOME project aims at developing a new user friendly technology for home automation based on voice command. This paper reports a user evaluation assessing the acceptance and fear of this new technology. Eight healthy persons between 71 and 88 years old, 7 relatives (child, grandchild or friend).

The current work takes a different route and explores whether the input or task initiation modality (i.e., the words consumers are required to use to command the conversational interface) can systematically alter consumers’ subjective task experience and their underlying attributions toward the interface. Building on recent conceptual foundations of consumer-smart-object experiences during IoT interactions (Hoffman and Novak 2018; Novak and Hoffman 2018), we examine how constricted task initiation modalities during human-object interaction can evoke more negative task experiences, more negative attributions toward the voice-based assistant, and even systematic changes in the vocal expressions consumers make when they issue spoken commands.

To explore whether and how variation in task initiation modalities affects consumers’ task experiences, we recruited 100 participants for a laboratory study in exchange for monetary compensation (M_{Age}=24.27, SD_{Age}=6.28, 51% females). At the outset of the study, we assessed participants’ baseline vocal features using an established reading task from prior work in bioacoustics (Kempster et al. 2009; e.g. “The blue spot is on the key again.”). Next, participants were randomly assigned to either a constricted versus non-constricted task initiation modality condition. In both conditions, participants were asked to state a set of eleven commands that required them to engage in a turn-taking exercise with Amazon Alexa. The two conditions differed systematically in the level of constriction: In the constricted modality condition participants received eleven commands that required a syntactically shortened form of interaction (e.g. “Alexa, length of marathon.”). In the non-constricted condition, participants received the same substantive commands but all were phrased in terms of a more natural conversation (e.g. “Alexa, can you tell me the length of a marathon?”). All commands were pretested to guarantee they led to identical responses of the voice assistant independent of task initiation modality. Next, participants were asked to rate: the perceived naturalness of the interaction (“The interaction with this interface felt … natural / robotic(r) / lacking depth (r)”, $\alpha_{natural}=79$), their overall task enjoyment (“This task was a lot of fun”), attributions of competence (“This system is … an expert / competent / proficient”, $\alpha_{comp}=.81$) and warmth (“This system is … compassionate / sympathetic / warm”, $\alpha_{warm}=.85$). Finally, they responded to a set of demographic questions. The audio data of the baseline reading task and the object-interaction task was recorded using an external BlueYeti microphone with a predefined sampling rate of 44100 HZ.
Processing of all audio data and extraction of vocal features at the participant level was done using the seewave and tuneR packages in R (Sueur, Aubin, and Simonis 2008).

As predicted, the results revealed that the constricted task initiation led participants to perceive the voice-assistant interaction as significantly less natural (M_constric = 3.70, M_nonconstric = 4.43; t(98) = 2.654, p < .01). Participants in the constricted task condition also enjoyed the task significantly less than the non-constricted condition (M_restrict = 4.18, M_nonrestrict = 4.96; t(98) = 1.675, p = .09). A mediation analysis also confirmed that the effect on task enjoyment was offset after controlling for the effect of perceived naturalness on task enjoyment (5000 bootstrap resamples; CI[95%] = [0.07; 94]), indicating full mediation. Greater perceived naturalness was also a key factor in predicting greater attributions of both competence (β_{natural} = .36, t(98) = 3.83, p < .001) and warmth (β_{natural} = .74, t(98) = 8.60, p < .001). A series of Davidson MacKinnon tests for non-nested models further revealed that including the fitted values of the attribution dimensions (competence and warmth) led to a significant improvement of model fit (θ_{natural} = .92, t = 4.413, p < .001) whereas including the fitted values of naturalness only model did not further improve the fit of the model (θ_{CompWarmthFitted(NaturaModel)} = .17, t = 0.575, p = .56), indicating that the attributions toward the system (evoked through perceptions of a more natural task experience) led to the increased task enjoyment.

The task-initiation manipulation also significantly altered participants’ vocal expressions. We find that constricted (vs. non-constricted) task initiation led to an increase in sound pressure levels relative to the baseline measure of the reading task (t(98) = 10.917, p < .001) and the between-subjects comparison of the object-interaction task (M_restrict = 8.9052, M_nonrestrict = 8.9044; t(98) = 3.242, p < .01). Similarly, constricted versus non-constricted task initiation also significantly increased participants’ vocal entropy relative to the baseline measure (t(98) = 13.819, p < .001) and during the object-interaction task (M_restrict = .69, M_nonrestrict = .66; t(98) = 4.167, p < .001). These findings suggest that constricting the structure of the task causes individuals to engage in a higher pitch and less fluent (or even “mechanistic”) vocal expression during speech formation. This change in individuals’ vocal features was also reflected in a significant, negative correlation between perceptions of naturalness and vocal entropy (r(98) = −.64, p < .001), confirming that the less fluent vocal expression was also associated with lower task enjoyment. Robustness tests to explore boundary conditions also support our main hypotheses, but are not reported here in the interest of space.

To our knowledge, this is the first work documenting that altering the input modality of how consumers interact with smart objects systematically affects their IoT experience. We provide evidence that altering the required input to initiate a conversation with smart objects provokes systematic changes in terms of objective phonetic vocal changes and, more importantly, consumers’ subjective experiences.

Improving Civil Discourse: Speaking is a More Civil Form of Discourse Than Writing

EXTENDED ABSTRACT

Political intolerance in the United States is at record levels. According to the Pew Research Center, in 2014 members of both political parties were more than twice as likely to report that the other party is a “threat to the nation’s well-being,” compared to 1994. Increasingly, people don’t just disagree; they also distrust, dislike, and even despise those who see the world differently. Exacerbating this problem, some evidence suggests that people are withdrawing from conversations with opposing party members. In 2016, just 6% of Americans reported having “many” close friends from the opposing party. Moreover, social media may increase ideological “echo chambers” in which people only interact with those who share their opinions.

What’s the solution? Many organizations are currently trying to encourage civil and respectful conversation among people who disagree, so that they can exchange their opinions and resolve differences. For example, Living Room Conversations, founded in 2010, “encourages conversation with those with whom we may not agree… to increase understanding and reveal common ground.” Another example is Pnyka, founded in 2017, a communication platform that “bridges divided communities by using respectful interactions.” But a major difference in how organizations are pursuing this solution is that some of them host conversations online (e.g., Pnyka) whereas others insist on hosting only in-person or video-chat conversations (e.g., Living Room Conversations).

This provokes an important psychological question: How does the communication medium of a conversation influence the civility of the discourse? The extant literature suggests that spoken (versus written) conversation may increase civility for at least three reasons: first, the paralinguistic cues in voice provide insight into a communicator’s thoughts and feelings (Schroeder & Epley, 2015, 2016; Schroeder, Kardas, & Epley, 2017), second, speaking is a more synchronous and “richer” medium (Daft & Lengel, 1984), and third, speaking includes more back-channeling (i.e., feedback that conveys understanding; Tollins & Fox Tree, 2014, 2016).

To test whether lay individuals share this intuition, two initial experiments (Exps. 1 & 2; n = 800) asked people to predict how having a ten-minute conversation with an ideological opponent via video-chat, phone, or writing (three conditions, within-subjects design) would change their assessments of the opponent and their experiences. Predictors tended to believe that the written conversations would be more civil—more shared understanding, less conflict, and more enjoyable (p < .01)—compared to phone or video-chat conversations (p > .01), although they expected no differences in how much they would perceive their opponent (i.e., how thoughtful, competent, and reasonable the opponent seemed) or change their own attitudes across conditions (p > .250). Overall, predictors reported a strong preference to write (M = 80%) compared to talk or video-chat (M = 20%).

We next tested whether these beliefs are correct in five more experiments. Experiments 3-6 each utilized a similar procedure whereby participants were matched based on disagreement according to pre-selected controversial topics, engaged in a 6 to 12 minute conversation (depending on the experiment) with an ideological opponent, and then reported conversation civility—humanization of their conversation-partner, attitude change, felt understanding, and conflict—in a post-conversation survey.

In Experiment 3 (n = 358), pairs interacted either by video-chatting, speaking (audio-only), or writing (three between-subjects conditions). Contrary to the predictions in Exps. 1-2, these participants reported engaging in more civil interactions with their partner when video-chatting or speaking versus writing (p < .01), but there was no difference in civility between video-chatting or speaking (p > .250).

Because participants produce about twice as many words in spoken versus written conversations, Experiment 4 (n = 796) next manipulated how long pairs conversed in a 2-speaking vs. writing x 2 (6-minute vs. 12-minute conversations) between-pair design. We replicated the effects from Exp. 3 such that the conversations were generally more civil when speaking (vs. writing), regardless of how
much time they spent conversing. There was no effect of time on any outcome variable.

Experiment 5 (n=396) attempted to control for synchronicity between communication-medium by using a 2(speaking vs. writing) x 2(dialogue vs. monologue) between-pair design. The dialogue condition used the same procedure from Exps. 3 and 4 but the monologue condition only allowed pairs to exchange opinions once. Results revealed that, even in the monologue condition, spoken conversations were more civil than written conversations (i.e., more positive impressions partner, more felt understanding, less conflict). This effect of communication-medium also replicated in the dialogue condition such that there was no statistical interaction between communication medium and synchronicity condition. A main effect of synchronicity condition also emerged; there was greater civility overall in the dialogue (vs. monologue) condition.

To further examine what is changing in the spoken versus written conversations, we asked 400 online observers to read transcriptions of the spoken or written “long” conversations from Exp. 2 (92 conversations total). Each observer reviewed just one conversation and then reported how much the pair understood, liked, and agreed with each other. Observers believed there was more understanding, liking, and agreement in the spoken (vs. written) conversations, suggesting that the effect of communication medium occurs even without hearing the interactants’ voices.

A follow-up experiment (n=400) further considered the trajectory of the conversations by asking online observers to rate each “exchange” of opinion within a conversation separately. Results from this experiment revealed that observers could tell the difference between the spoken and written conversations almost immediately—by the second exchange of opinion in the conversation. In aggregate, the results from these eight experiments suggest that, although people seem to prefer writing to (vs. speaking with) an opponent, in fact speaking is more civil form of discourse. Political opponents who had short spoken conversations reported having more positive impressions of each other, experiencing less conflict, feeling more understood, and being more open to each other’s attitudes compared to opponents who had written conversations. These findings have important implications for how technology may shape discourse. People who disagree can easily interact via online forums (e.g., Reddit, Facebook), which may discourage them from conversing in-person. Further, these online interactions may subtly exacerbate conflict. Disagreement is born not just from harsh words exchanged but from the structure of the interaction itself.

SYMPOSIUM OVERVIEW
The growth of the luxury market (from a $80 to a $900 billion industry within the last two decades, reaching by now 450 million brand users) has been a significant consumer phenomenon. As luxury is moving from a concept associated with status elitism toward global brand appeal, luxury is exposing itself, and likely to be influenced by, new consumer trends, cultural associations, and social-moral issues. These developments seem to lead to a refocus and challenge of the very nature of luxury, raising new theoretical issues for consumer researchers. The four papers in this session address these conceptual issues and provide timely insight and novel findings on new consumers such as Millennials and explore new marketing strategies and approaches in luxury retail, product design and promotion.

The first paper examines what Millennials, the new consumers of luxury goods, value and care about in luxury consumption. Three experiments show that the role of luxury brands as status has not fundamentally changed for Millennials. What has changed, however, is what constitutes “status.” For Millennials, luxury is used as expression of their values. Thus, luxury is not wealth-as-status, but rather values-as-status.

The second paper explores how the increasing collaborations between arts/artists and luxury retail can impact consumers’ desire for luxury goods. Two field studies and four experiments demonstrate counter-intuitively that the appreciation of art decreases consumers’ desire for luxury brands. Viewing art seems to induce feelings of transcendence and therefore lead to a decrease of desire for status products such as luxury goods.

Ethical concerns (i.e., the damage or destruction of environmental resources to produce a luxury product) poses new challenges for luxury brands. The third paper examines this challenge and explores how consumers react to the environmental costs of production of luxury goods. Four experiments show that for status-striving consumers, the environmental costs of production make status products more, rather than less, appealing. This is because such products enable consumers to reach higher social status by feeling dominant.

The final paper in this session focuses on a new promotion strategy, the use of aggressive imagery, to investigate when and why aggressive (vs. neutral) imageries may increase consumers’ desire for luxury brands. Three experiments show that using aggressive imageries increases the attractiveness of luxury brands among consumers low in dominance. This is because low-dominance (but not high-dominance) orientation consumers see in aggressive luxury brands a promise of empowerment.

Taken together, this session shows how researchers need to deconstruct—and reconstruct—luxury and the constructs associated with it in contemporary consumer society. The set of papers thus opens up several new avenues of research in the area of luxury and status consumption. Each paper includes several experiments and provides process evidence for the proposed constructs, which can stimulate new research and provide practical insights in the area of luxury and status consumption. Given the variety of settings and broadly relevant questions, this session is likely to have wide appeal, attracting conference scholars interested in status goods, social signaling, and branding.

From “Wealth-as-Status” to “Value-as-Status:” The Millennial Luxury Consumer Mindset

EXTENDED ABSTRACT
For luxury marketers, attracting the new Millennial consumer is key to achieving sustained growth for the luxury brand. Bain & Company and Farfetch (2017) report that Millennials will represent 40% of the market by 2025. This “Millennial generation” are a challenge for luxury marketers since they question the foundation from which they operate. As Kapferer (2015, p. 1) states “luxury is an industry like no other: it is the only one for which growth creates a problem”. This raises the question: What do Millennial consumers care about?

The marketing literature has argued that luxury brands are “good” signals of status. Luxury brands are a means by which to indicate where one is on the social ladder, and where one intends to go (Belk, Bahn, and Mayer 1982; Amaral and Loken 2016). This literature argues that while luxury status signals may be conspicuous (Han, Nunes, and Dreze 2010) or inconspicuous (Berger and Ward 2010), luxury brands help consumers gain social approval and fit in with their social group (social-adjustive function) (Wilcox, Kim, and Sen 2009). And yet, signals of status seem to be changing. Recent literature suggests that larger-sized food and drink options (Dubois, Rucker, and Galinsky 2012), non-conforming behaviors (Bellezza, Gino, and Keinan 2014), and “busyness” (Bellezza, Paharia, and Keenan 2017) serve as new symbols of status. Germane to this research is the finding that status can be achieved by engaging in more prosocial behaviors (choosing green alternatives; Griskevicius et al. 2010).

Integrating these new theories of status with the functional theories of attitudes (Katz 1960; Shavitt, Lowrey, and Han 1992), the current research seeks to explain why luxury consumers (Millennial versus not) are drawn to luxury brands. Wilcox et al. (2009) demonstrated that attitudes serve important social functions allowing consumers to express their central values (value-expressive function) or to help them gain social approval (social-adjustive function). In the current research, we begin with the hypothesis that the functional role of luxury (social-adjustive) that is provided to consumers, Mil-
lennials or not, has not fundamentally changed. However, what is signaled – i.e., what constitutes “status” – has likely changed. We therefore expect that while other cohorts use luxury to signal “wealth as status”, the basis for the social-adjunctive function of luxury brands for Millennials is rooted in core Millennial values, i.e., “values as status” (Sim 2018).

Three experiments support our theorizing. In a pilot Study (N = 100, Mturk, 57% female), we recruited Millennial, Gen X, and Boomer consumers who owned at least one luxury product to determine motivational differences in luxury purchases across generations; specifically, we asked the extent to which brand name, uniqueness, social-adjunctive and value-expressive motivations (Wilcox et al. 2009) drove their purchase. Interestingly, we found no significant differences suggesting that even though the expressive and signaling functions haven’t changed, what is signaled, however, could be different for Millennial consumers.

To test this assumption, in Study 2 (N = 188, University Laboratory, 53.7% female), we employed a 2x2 design by manipulating both generational values (GV; Millennial vs. Non) and luxury perceptions (Traditional vs. Sustainable). We manipulated GV by creating mock websites for “Arete,” a luxury hotel in Greece, but described the hotel as a traditional (e.g., Michelin-star rated chef) vs. sustainable (e.g., locally sourced organic ingredients) luxury hotel. Participants reported (al 1-7 scales) purchase likelihood for the trip, their brand attachment to and brand love for the Arete brand, and if they wanted to be contacted by a reservation specialist to help them plan the trip in the future. A two-way ANOVA on purchase likelihood found a marginal main effect of luxury type (MTraditional = 4.49 vs. MSustainable = 4.88, F(1, 184) = 2.882, p = .091), a main effect of GV (MMillennial = 4.42 vs. MNonMillennial = 4.95, F(1, 184) = 5.150, p = .024), and a significant interaction (F(1, 184) = 12.536, p = .001) such that when participants were purchasing for themselves, they were more likely to buy the trip when the hotel was framed as sustainable luxury (MMillennial Sustainable = 5.02 vs. MMillennial Traditional = 3.82, t(89) = 3.509, p = .001), while they were more likely to buy the trip for their parents when the hotel was framed as traditional luxury (MNonMillennial Sustainable = 4.73 vs. MNonMillennial Traditional = 5.16, t(95) = -1.377, p = .172). A moderated mediation analysis (Hayes 2013, Model 8) with GV as the independent variable, luxury type as the moderator, brand attachment as the mediator, and purchase likelihood as the dependent variable, demonstrated that brand attachment mediated the effect of luxury type on brand attachment, but only for the Millennial consumer when the hotel was framed as sustainable luxury (index of moderated mediation: [CLL; .058; .915]; indirect effect when luxury = sustainable: b = -.400, SE = .195, CLb = -.841; -.081). We found a similar pattern of results for brand love (interaction: F(1, 184) = 5.653, p = .018), and whether they wanted to be contacted by a reservation specialist in the future (interaction: F(1, 184) = 4.038, p = .046). This study supports our theorizing that Millennials use luxury as a way to obtain status by signaling salient values for their cohort.

Finally, to assess whether this “values-as-status” framework applies to all vs. only luxury consumption, in Study 3 (N = 141, University Laboratory, all female Millennials) we randomly assigned participants to either a luxury (vs. non-luxury) condition, in which they read about a brand of luxury (vs. non-luxury) skins. We replicated the main effect of luxury on social-adjunctive motivations, such that the participants who imagined owning the luxury pair of skins were more likely to exhibit social-adjunctive motivations relative to the participants imagining the non-luxury pair of skins (Mluxury = 4.43 vs. MNonluxury = 3.48, F(1, 139) = 11.826, p = .001). Participants in the luxury condition exhibited higher brand attachment than participants in the non-luxury condition (Mluxury = 2.91 vs. MNonluxury = 2.44, F(1, 139) = 4.587, p = .033). A mediation analysis (Hayes 2013), demonstrated how the social-adjunctive motivations mediated the effect of luxury consumption on brand attachment [CLm = .081; .360].

Taken together, these findings suggest that Millennial luxury consumers purchase luxury to convey status, but not wealth-as-status, but rather values-as-status.

Picasso, Monet, and Louis Vuitton: Appreciation of Arts Dampens Desire for Luxury Goods

EXTENDED ABSTRACT

The high-end fashion market has witnessed increasing collaborations between arts and luxury brands. Ermenegildo Zegna, an Italian luxury fashion house that specializes men’s clothing and accessories, initiated the ZegnaArt project in 2012, supporting artists across the globe and exhibiting their artworks in Ermenegildo Zegna’s retailing stores around the world. Other brands, such as Cartier, Louis Vuitton, Gucci, and Prada, operate their own museums to preserve their brand heritage and promote the brand. The above efforts of bringing art experiences into high-end shopping are with the hope that artistic retail environment and luxury goods can create positive synergies. However, little work has investigated the real impact of art experience on consumers’ reactions towards luxury consumption. One stream of research found that incorporating art into the design of the product (e.g., package of the product, the advertising) would have a positive impact on consumer perceptions and evaluations of the product (i.e., art infusion effect; Hagtvedt and Patrick 2008a). Such positive effect occurs because the artworks activate connotations of luxury and exclusivity, which spills over to enhance the perceived luxury of the product (Hagtvedt and Patrick 2008a). In this and other related work on the transfer of luxury from perceptions of artworks to perceptions of products (Hagtvedt and Patrick 2008b), the artworks need to be an integral part of the product itself or part of its brand image. However, little evidence is available to show how the presence of artworks in a luxury retail environment, which are not part of the product itself, may influence consumers’ consumption behaviors. The present research fills in this gap in literature and investigates the influence of exposure to unrelated artworks on consumers’ desire to consume luxury products.

We propose that appreciating artworks can elicit a feeling of self-transcendence, which refers to the experience of perceiving expanded boundaries of the self (Reed 1991; Schwartz 2012). This experience allows people to feel connected to the larger context of existence and perceive the self to insignificant. As a result, this feeling of self-transcendence may undermine the need for self-enhancement, which has been established to drive luxury consumption. We also propose that activating pragmatic goals while view artworks (such as judging the market value of artworks or analyzing the technical details of artworks) interferes with the art appreciation experience, and thus, attenuate the proposed effect.

We conducted one pilot study, two field studies, and four additional lab studies to test our hypotheses.

In the pilot study, participants either visited an art gallery or a student center (control) on campus. Upon touring around, participants responded to a scale assessing their feelings of self-transcende-
dence (e.g., I feel that my individual life is a part of a greater whole; I feel free from daily utility concerns). The results revealed that participants expressed stronger feeling of self-transcendence after viewing artwork in the art gallery than those in the control group did (p < .03). Therefore, appreciating artworks indeed induced feelings of self-transcendence.

Building on the pilot study, the first field experiment tested the influence of viewing an art exhibition in a subway station on consumers’ choice to browse either the website of a luxury shopping mall or that of a regular shopping mall. The results provided initial support to our hypothesis by showing that viewing (vs. not viewing) famous artworks decreased consumers’ likelihood of browsing the website of the luxury shopping mall (p < .03).

The second field experiment surveyed consumers’ interest in receiving promotional materials from either luxury or non-luxury brands (i.e., in forms of choice) before or after exposure to a real, artistic shopping environment. Consistent with the findings in experiment 1, experiment 2 showed that consumers were less likely to choose to receive promotional materials from luxury brands (vs. non-luxury) after (vs. before) being exposed to an artistic shopping environment (p < .01). Experiment 2 also included control conditions showing that exposure to a non-artistic shopping environment did not affect consumers’ choice between luxury and non-luxury brands (ns).

Experiment 3 and Experiment 4 provided additional support for our hypothesis in more controlled lab settings using a behavioral measure and an incentive compatible measure. In these experiments, participants viewed either images of artworks or images of photographs that were matched on the content. Then, they designed luxury products by drawing logos luxury brands on them or chose a gift card that is either from luxury or regular brands. The results revealed that after viewing artworks (vs. viewing non-artistic photographs), participants drew smaller logos in product design (p < .02) and were more likely to choose the regular (vs. luxury) brand gift card, reflecting their reduced desires to consume luxury products (p < .02).

We further tested our theorizing by exploring important boundary conditions in Studies 5 and 6, both of which dampened the feeling of self-transcendence and erased the effect. Specifically, in addition to manipulating viewing or art vs. non-art images, Experiment 5 primed thoughts about the market value of artworks (vs. no prime) and Experiment 6 manipulated attention to technical details of artworks while viewing them (vs. not). The results showed that when pragmatic goals were not primed, the negative effects of art appreciation on desire for luxury goods were replicated (ps < .01 for the simple effect of art in both studies). However, priming of pragmatic goals interfered with art appreciation process to remove the feelings of self-transcendence, and consequently muted the negative impact of viewing art on consumers’ intention to shop and consume luxury products (ns for the simple effect of art in both studies; ps < .05 for goal prime x art interaction in both studies).

**Hurts So Good: Status Products That Incur Environmental Costs Are Preferred by Status-Striving Consumers**

**EXTENDED ABSTRACT**

Consumers often face an ethical dilemma when considering the purchase of status products (Griskevicius, Tybur, and Van De Bergh 2010) because of the negative environmental impact necessary to their production. Notwithstanding the negative perception of the environmental and ecological toll of the production of status products, we propose that for some consumers, it is this very impact which makes the products appealing.

Humans’ status hierarchies differ from those of other primates in several important ways, one of which is that the repertoire of dominance behaviors is greatly expanded beyond demonstrations of physical strength. Thus, dominance can be applied and understood symbolically. Specifically, products that have inputs that have explicitly destroyed, killed, or egregiously harmed a natural resource symbolically express the producer’s (and by extension, the consumer’s) dominance over another living being or resource.

Given that environmental costs symbolize one’s dominance over the natural world, luxury products that incur such costs offer a potent symbol of social status because they represent not only prestige, but also dominance. The Dominance-Prestige account of status-striving (Henrich and Gil-White 2001) states that individuals may increase their social status by engaging in behaviors that express both prestige and dominance. Dominance entails behaviors that induce fear through intimidation (Chase et al. 2002), while prestige refers to the influence based on skills, access to material resources, or knowledge (Cheng and Tracy 2014). Thus, it is likely that individuals who are striving for status will be particularly attracted to products associated with both prestige and dominance, such as luxury products that incur environmental costs.

Research examining how product consumption relates to status finds that individuals striving for status are often attracted to luxury goods (Braun and Wicklund 1989; Wicklund and Gollwitzer 1981) or “prestige goods” in order to affirm desired identities (Ward and Dahl 2014). While luxury products universally represent prestige, we propose that the subset of luxury products that incur environmental costs are also emblematic of dominance and thereby represent both paths to social status. Therefore, we predict that consumers who are strongly motivated to attain social status will find luxury products known to incur environmental costs more appealing compared to products that do not incur such costs. The reverse should be true, however, for consumers who are less motivated to attain social status.

One of the consistent traits of status products is that consumers perceive them as scarce (Cialdini 1984; Dubois, Czellar, Laurent 2005). While some might view scarcity as the inevitable result of the environmental costs inherent in the production of luxury products, scarcity and environmental costs are orthogonal constructs. That is, there are environmental costs that do not result in scarcity and, conversely, certain scarce resources are not the consequence of environmental costs. Thus, we acknowledge the importance of scarcity in consumers’ desire for luxury. However, in our studies controlling for scarcity perceptions did not change the pattern or significance of our results.

Study 1 was a 2 (environmental costs: high vs. low) x 2 (status-striving: high vs. low) behavioral study (n = 205). First, participants were instructed to write about why choosing status goods either makes sense (high status-striving condition) or does not make sense (low status-striving condition). After the prime, an RA asked participants to take part in a taste test for a luxury cold-pressed juice brand. Those who agreed read about juice made from Camu Camu fruit. Only in the high environmental cost condition were participants told that harvesting the fruit has a detrimental effect on the fauna and flora surrounding it. Participants were then given one-ounce samples of the juice, which was actually a mixture of several other juices. Participants endorsed the degree to which they liked the juice, found the juice desirable and thought it tasted good (1 = not at all/ 9 = very much; α = .94). Participants in the high status-striving condition found the juice with high environmental costs to be more appealing compared to the juice with low environmental costs ($M_{HEC} = 6.97$ vs. $M_{LEC} = 5.93$, $F(1, 202) = 9.38$, $p = .002$). This pattern was reversed in the
low status-striving condition ($M_{REC} = 6.01$ vs. $M_{L = E} = 6.59$, F(1, 202) = 2.64, $p = .10$).

Study 2 manipulated one between-subjects factor (environmental costs: high vs. low) and measured status-striving (Eastman et al. 1999). Participants ($n = 131$) were told that the marketing department was working with the university bookstore to determine which kind of luxury chocolate squares they should carry. At each computer was 10 chocolate samples and a booklet offering information about the luxury chocolate. Only in the high environmental cost condition did participants read that cocoa farming contributes to deforestation and damage to wildlife habitats. Before leaving, participants were told they could take as many chocolate samples from their stations as they liked. RAs recorded how many chocolates participants took (0-10). Approximately two weeks later, a follow-up email survey measured status-striving (Eastman et al. 1999) and other demographics. For high status-strivers (+1 SD), the presence of high environmental costs caused an increase in the number of chocolate samples taken ($\beta = .43, p = .0002$). For low status-strivers (-1 SD), the presence of high environmental costs caused a decrease in the number of chocolate samples taken ($\beta = -.33, p = .03$).

Study 3 examines our hypothesized dominance process via moderation. We conducted a 2 (environmental cost: high vs. low) X 2 (dominance: validated vs control) between-subjects design with status-striving measured. First, participants ($n = 323$) were primed by writing about a time that they had felt dominant (dominance validated condition) or to describe their typical morning routine (control). Then, they were instructed to read a passage about how snakeskin is procured for luxury accessories. In the high (low) environmental cost condition we included information that the snakes were killed for their skins (molted their skins). Then all participants rated a black luxury “weekender” bag made of snakeskin on how attractive, appealing, and desirable the bag was (1 = not at all/9 = very much; $\alpha = .91$). Finally, they completed the same status-striving scale used in Study 2 (Eastman et al. 1999).

In the control condition, where dominance had not been validated, we continue to find a significant and positive effect of environmental costs at high status-striving (JN point at +1.66 SD), and a significant and negative effect of environmental costs at low status-striving (JN point at -4.55 SD). Our prediction was that when status-striving participants are validated in their feelings of dominance, they would find status products that incur high environmental costs to be less appealing, as they no longer need to consume items that represent this personal quality. In the high environmental cost condition, the effect of the dominance manipulation on product appeal was negative and significant at high levels of status-striving (JN point at +4.2 SD).

In Study 4, we investigate whether our results are the outcome of environmental costs or simply a function of the excessive effort required to create the product. Given our theorizing regarding the role of dominance, we predict that our effects will be attenuated when the production process does not incur environmental costs, as the item will not represent the desired trait of personal dominance. Study 4 was a 2 (procurement: environmental cost vs. excessive effort) x 2 (status-striving: high vs. low) between-subjects design. Participants ($n = 198$) began by completing the same status-striving prime used in Study 1. Then participants read an excerpt from a luxury magazine that discussed the procurement of cultured pearls. In the excessive effort condition, the article indicated that procuring the pearls is safe for the ecosystem, but requires an excessive amount of effort on the part of the producer. In the environmental cost condition, the article explained that to create cultured pearls, the ecosystems (where the oysters are found) are destroyed. After reading the article, participants rated a pearl brooch on how attractive, appealing, and desirable it was (1 = not at all/9 = very much; $\alpha = .82$). There was no effect of procurement in the low status-striving condition ($M_{REC} = 5.08$ vs. $M_{L = E} = 5.88$, F(1, 194) = 2.52, $p = .11$, $\eta^2 = .013$). However, in the high status-striving condition, participants found the pearl brooch in the environmental cost condition to be more appealing ($M_{REC} = 6.32$ vs. $M_{L = E} = 5.07$; F(1, 194) = 4.75, $p = .03$, $\eta^2 = .024$).

In sum, we contend that certain consumers (those striving for status) are drawn to status products because they are destructive to environmental resources. Consuming these products enables consumers to access an object that represents an additional path to high social status: dominance. Thus, we find support for our prediction that objects that embody both signals (prestige and dominance) are a stronger representation of status and, as such, are particularly appealing to status-striving consumers.

Do Fighters Wear Prada? Consumer Dominance Orientation and Desire for Luxury Brands

EXTENDED ABSTRACT

Consider the 2017 award-winning perfume ad World, by Kenzo, featuring Margaret Qualley firing missiles, roaring like a beast and beating security agents in an opera. This ad is an exemplar of a recent wave of luxury communications by brands such as Dolce and Gabbana, Dior or Cartier, emphasizing aggressive imaginations. Such a dominant strategy contrasts with the historical role of luxury goods as symbols of high standing, refinement and prestige (Dubois and Ordabayeva 2015).

The current work investigates when and why aggressive imaginations, reflecting a dominance orientation, may increase consumer desire for luxury brands. Dominance orientation refers to the use of strength, aggression and intimidation to obtain/withhold status — in opposition to prestige orientations (Cheng et al., 2013; Maner, 2017).

With this work, we extend prior research, within the luxury space, showing that salespersons’ aggressiveness, can underlie luxury brands’ status and superiority in customers’ eyes (Dion & Arnold, 2011; Dion & Borraz 2017; Ward & Dahl, 2014).

An exploratory coding of 200 perfume brand names shows that male fragrances have more aggressive names ($M = .14$) than female fragrances ($M = -.04$; $F(1, 198) = 3.65, p = .06$), suggesting that brands may intuitively target consumers high (vs. low) in dominance with aggressive imaginations.

In contrast to this tendency, past work suggests that consumers low (vs. high) in dominance, may desire more aggressive imaginations. For instance, it may help consumers increase their status in hierarchies where dominant behaviors are predominant (Maner, 2017). The greater the need to behave dominantly, the greater the reliance on luxury brands that use an aggressive imagery. Thus, consumers may be attracted by aggressive imaginations to compensate for their own lack of dominance orientation. In support, threatened consumers often desire to purchase luxury goods to offset a threat or compensate for their powerlessness (Lee & Shrum, 2012; Rucker & Galinsky, 2008).

Building on this research, we propose that dominance orientation moderates the desire for luxury brands that use aggressive imaginations such that aggressive imaginations increase the attractiveness of luxury brands among consumers who need to behave dominantly, because these consumers perceive that luxury brands offer them an opportunity to be empowered (Wathieu et al., 2002).

Three studies test our predictions.

Study 1 provides evidence that an aggressive imagery increases the desire for the luxury brand for participants who need to behave dominantly (vs. do not) to acquire status. Specifically, this study (N=177) examines the role of status goals (neutral vs. prestige vs.
dominance) on the preference for an aggressive (vs. neutral) luxury ad. We manipulated status goals by asking participants to imagine themselves in a group, with a desire to gain status. Key to the manipulation, status was defined as “the ability to impose one’s will on the others” in the dominance goals condition, but “admiration and respect from the others” in the prestige goals condition. There was a significant interaction of aggressive imagery x status goals on ad liking ($F(2, 171) < 2.99$, $p < .05$). In both the neutral and prestige conditions, participants did not exhibit greater desire for the ad using an aggressive (vs. non-aggressive) imagery ($F(1, 171) < 1.38, p > .24$). However, participants expressed greater liking when the ad featured an aggressive imagery ($M = 4.87$) than when it did not ($M = 3.91; F(1, 171) = 5.60, p = .02$) in the dominance goal condition.

To support the mediating role of empowerment potential and the moderating role of consumer dominance, in Study 2 ($N=466$), participants evaluated another luxury ad (aggressive vs. neutral). At the end of the survey, they completed a scale measuring their dominance orientation. Results showed that participants preferred the luxury brand after observing the aggressive (vs. neutral) ad ($\beta = .75, t(462) = 2.19, p = .03$). The aggressive imagery x dominance orientation interaction on brand liking ($\beta = -.13, t(462) = -1.67, p < .10$) revealed that the preference for aggressive images was driven by participants who had low (but not high) dominance orientation. Further, aggressive imagery increased the perceived empowerment potential of the brand ($\beta = 1.20, t(462) = 4.29, p < .001$), and this effect was moderated by participants’ dominance orientation ($\beta = -.22, t(462) = -3.50, p < .001$). A moderated mediation analysis (Process, Model 8; Hayes & Preacher, 2013) revealed a significant index of moderated mediation ($a = -.17, 95% CI = [-.2801, -.0582]$).

Study 3 ($N=354$) provides further evidence for the mediating role of empowerment potential, by showing that the positive effect of aggressive imagery on brand/ad liking occurs when the model of the ad has a high empowerment potential (i.e.; female model), but not when he has a low empowerment potential (i.e.; male model). Participants consecutively evaluated two similar luxury ads (one with a female model and one with a male model) for the same brand, which were neutral or featured an aggressive imagery ($F(1, 352) = 5.51, p = .02$) and the brand ($F(1, 352) = 4.09, p = .04$) when shown an aggressive (vs. neutral) ad with a female model. Neither of these effects was moderated by gender ($|t| < .32, p > .74$), showing that the effect does not exclusively work with female consumers. However, these effects do not appear with ads featuring a male model ($FS < 1.73, ps > .19$).

Planned studies include comparing the effect aggressive imagerys in luxury versus non-luxury contexts. A first investigation ($N=266$) showed that aggressive ads (vs. neutral) increase the perception of empowerment potential for luxury brands ($F(1, 262) = 10.79, p = .001$), but not for non-luxury brands ($F(1, 262) = .038, p = .54$). This result needs to be confirmed in a study examining further consequences on brand liking.

Overall, the current work examines situational and chronic moderators of when consumers with high need for dominance express greater desire for aggressive (vs. neutral) ads and brands. This research contributes to the literatures on luxury consumption, aggression, compensatory mechanism and social dominance.

Paper #4: Hot or Cold? How Ambient Temperature Influences Calorie Consumption

Jayesh Sinha, Florida International University, USA
Rajesh Bagchi, Virginia Tech, USA

SESSION OVERVIEW

Ambient sensory factors play critical roles in unconsciously and subconsciously influencing consumer product judgments and choices (Krishna 2012). Prior research has examined the role of different sensory ambient factors such as scent (Biswas and Szocs 2019; Madzharov, Block and Morrin 2015), sound (Sayin et al. 2015), and décor (Bell et al. 1994), among other factors. In this proposed special session, we extend this research stream and examine how ambient visual and haptic factors non-consciously influence consumer product evaluations, choices, and consumption.

The first paper zeroes in on effects of visual cues associated with a package on food purchase behavior. The second paper zooms out and examines perceived directionality of lighting on a product and its effects on purchases of food and non-food products. The third paper zooms out further and examines the effects of ambient visual cues, in the form of ambient color, on food purchases. While the first three papers examine the role of ambient visual cues, the fourth paper zooms out to a more subliminal sensory stimulus in the form of ambient temperature (which is a haptic stimulus) and its effects on food consumption.

To elaborate, in the first paper, Chandon and co-authors conducted a large-scale field experiment in 60 French supermarkets for three months to examine how front-of-package (FOP) labels influence the nutritional quality of food purchases. They found that design choices mattered more than whether the label graded the overall nutritional quality of the food on a single dimension (synthetic label) or provided information on calories, fat, sugar, and salt (analytic label). Sample and Sevilla, in the second paper, demonstrate how consumers' reliance on visual information is influenced by perceived lighting directionality. They find that products that provide benefits (eliminate issues) are preferred when lit from above (below) due to a match between lighting direction (coming from above or below) and metaphorical interpretations of provision and elimination properties. In the third paper, Biswas, Szocs, and Abell conducted a series of field and lab studies to demonstrate how red (vs. blue or white) ambient colors enhance consumer arousal levels, which in turn influence the indulgent level of the food purchased or preferred. In the fourth paper, Sinha and Bagchi investigate how ambient temperature (67-77°F) in typical consumption settings, such as at a restaurant or at home, influences calorie consumption. Through a series of field and lab studies, they demonstrate that as ambient temperature increases, calorie consumption decreases due to social density perceptions.

Together, the four papers in this proposed special session aim to address important research questions related to how subtle sensory factors like visual and haptic stimuli can influence product choices and consumption. The four papers complement each other. While all of them focus on ambient sensory stimuli (visual or haptic related), they have different degrees of zoomed-in versus zoomed-out focus, as mentioned earlier. Also, this set of papers focuses primarily on food related outcomes with the second paper also examining non-food outcomes.

Effects Of Synthetic and Analytic Graphical Front-of-Pack Labels on the Nutritional Quality Of Supermarket Food Purchases: Evidence from a Large-Scale Randomized Control Trial

EXTENDED ABSTRACT

To promote healthy eating, the European Union recently introduced new regulation allowing information about nutritional product quality to be placed, on a voluntary basis, on the “front of pack” (FOP) of the food product. Prior research has shown that graphical nutrition labels are liked by consumers (Feunekes et al., 2008) but there is sparse research on their impact in real-life shopping conditions (Cecchini and Warin, 2016, but see Nikolova and Inman, 2015 for an exception). An important unresolved question is whether synthetic systems, which grade overall nutritional food quality on a single dimension, outperform analytic systems, which provide detailed information on calories, fat, sugar, and salt. As a result, health authorities and food companies disagree on which system is best to improve the nutritional quality of food purchases.

To answer these questions, the French Health Ministry commissioned the authors to supervise a large randomized controlled trial comparing the effects of two synthetic labeling systems (SENS and Nutri-Score) and two analytic systems (Nutri-Repère and Nutri-Couleurs), chosen following a comprehensive consultation process.

FOP labels were put on packages of food products in 10 randomly-selected supermarkets per labelling system. In addition, twenty control supermarkets were randomly chosen. Consumers were informed of the local intervention in each treatment supermarket through leaflets and displays. Stickers were affixed to food products in four categories: fresh prepared foods, pastries, breads, and canned prepared meals. Participation by the manufacturers was on a voluntary basis, by design, as per EU regulations (only back panel nutri-
tion information is mandatory). The large majority of manufacturers and all three retailers agreed to participate. Once a firm agreed to participate, all of its products were labeled.

We evaluated the performance of the labeling systems in two ways. First, we computed a weighted average of the nutritional quality of the foods bought by each shopper. Nutritional quality was assessed using the nutrient profiling score developed by the British Food Standards Agency (FSA). The FSA score can range from -15 (best) to +40 (worst nutritional quality). We chose the FSA score as a measure of nutritional quality because its association with metabolic syndrome, cancer, and cardiovascular risks has been established in large cohort studies (Adriouch et al., 2016).

The second dependent variable examines the effects of the labeling systems on the purchase incidence of foods with low, medium, and high nutrition quality, by category. To do this, we first divided the products into terciles, based on the FSA score in each category, and estimated the average purchase incidence of the products in each FSA tercile. Unlike the basket analysis, which only looks at consumers who bought at least once in the category in 2015 and 2016, the purchase incidence analysis takes into account all consumers who visited the stores during the study periods.

We estimated the average treatment effects through a difference-in-differences analysis. This approach accounts for any differences between treatment and control groups from data outside the treatment period. Among synthetic labels, Nutri-Score again outperformed SENS, significantly at 5%. Among analytic labels, Nutri-Repère significantly outperformed Nutri-Couleur.

Looking at purchase incidence at high, medium, and low nutritional quality products, we find again that both synthetic systems have significant results in the desired direction. Both Nutri-Score and SENS improve the amount of purchase incidence of healthier products, with positive coefficients for the first tercile, and/or decrease the purchase incidence of unhealthier products, with negative coefficients for the third tercile. On the analytic labels side, Nutri-Couleurs also does well in that category.

Overall, the distinction between synthetic labels and analytic labels mattered less than the specific design choices of each labeling system. On that point, Nutri-Score outperformed the other systems, most likely because its ruler design and choice of colors and labels (A to E, green to red) provide an easier way to evaluate the relative nutritional quality of the food. However, the key conclusion is that these FOP systems, which had shown promising results in laboratory and online studies, had disappointingly small results in the field (all Cohen’s d were below 0.02) and not even always in the expected direction. This underscores the importance, for policy recommendation, of conducting studies in the field, in collaboration with producers, retailers, and health authorities.

### Going My Way? The Effect of Perceived Lighting on Perceptions of Provision and Elimination

**EXTENDED ABSTRACT**

Whereas prior research has examined the influence of the brightness of ambient light on consumer behavior (Biswas et al., 2017; Huang, Dong, and Labroo 2017; Xu and Labroo 2014), we study lighting from a different perspective—lighting directionality. Extant research has noted that consumers see ambiguous objects lit from above as closer (i.e., coming) and lit from below as farther (i.e., going; Hess 1950; Gibson 1950; Ramachandran 1988). We extend this phenomenon to complex product shapes that have a discernable top and bottom, demonstrating that a product can be perceived as coming (lit from above) or going (lit from below). Further, in alignment with past work noting how product properties can have metaphorical associations and perceptual influences (Deng and Kahn 2009; Nelson and Simmons 2009), we examine how perceived lighting directionality may interact with the prevalent product properties of provision (i.e., giving a benefit) and elimination (i.e., removing an undesirable condition). We argue that provision properties evoke perceptions of arrival (i.e., coming). Conversely, we argue that elimination properties generate perceptions of departure (i.e., going). Together, perceived lighting and provision/elimination properties interact to shape consumer preference. Specifically, consumers prefer lighting from above (below) for provision (elimination) products, as this matches the metaphorical interpretation of a provider (eliminating agent) coming towards (moving away) from a consumer. Two pretests and four studies investigate this novel area.

The first pretest (N=89) establishes that a product lit from above (vs. below) is perceived as coming (vs. going), whereas the second pretest (N=131) establishes that consumers hold metaphorical interpretations of coming (vs. going) for provision (vs. eliminating) properties.

In study 1, undergraduates (N=127) were asked: “Which one of these pictured mouthwashes seems better at ‘providing fresher breath’ (‘eliminating bad breath’)?” They were also presented with an image of a mouthwash with a logo lit from above or from below resulting in a 2 (providing vs. eliminating) X 2 (light from above or below) mixed design. Logistic regression reveals a significant effect (β=.511, χ²(1)=7.517, p=.006), such that participants in the provision condition preferred light from above, whereas those in the elimination condition preferred light from below.

Study 2 (N=444) replicates this effect in a similar paradigm where the dependent variable was preference for the product. An ANOVA examining preference reveals a significant interaction (F(1,440)=10.649, p=.001), such that consumers prefer products lit from above (below) claiming to provide (eliminate). Simple effects were also significant.

Study 3 showed that the effect leads to downstream consequences. Participants (N=225) were randomly shown one pair of images with a claim of either provision or elimination on both advertisements. There was one experimental image, with lighting from above or below, and one control image with no apparent directional lighting, resulting in a 2 (claim: provision vs. elimination) X 2 (perceived lighting: above vs. below) between-subjects design. Thus, every participant saw a control image with no directional lighting. Participants were asked which product they preferred, would be more likely to purchase, and would pay more for on three different pages. Logistic regression reveals a significant interaction for preference (β=.581, χ²(1)=17.287, p<.001) and significant simple effects for both provision and elimination. Similar interactions and simple effects were found for purchase intentions (β=.510, χ²(1)=13.507, p=.004) and willingness to pay (β=.399, χ²(1)=8.452, p=.004).

Finally, the process of this phenomenon is addressed in study 4 by exposing the role of the perceptual system. For both provision and elimination, the same order of events should occur for consumers. For instance, a providing or eliminating agent must first come from afar toward a consumer to provide a benefit (take something away) and then this agent departs. Thus, even though consumers focus on different parts of the act dependent upon it being an act of provision or elimination, the same process needs to occur. Therefore, to demonstrate the role of these perceptual expectations, we sought to interfere with this process by exposing participants to a proximity manipulation (focus on something very close). In contrast, participants exposed to a proximity control (focusing on something far away) would exhibit the same preferences as in prior studies. Thus, we un-
ticipated that participants exposed to the proximity control would exhibit the same preferences as in prior studies, whereas those exposed to the manipulation would have their perceptual expectations disturbed such that preferences would be no greater than chance.

For the proximity part of the study, undergraduates (N=159) were told to spend some time imagining a car being very close (far away) for the control (manipulation), and this was followed by a few inconsequential questions. In a subsequent study, participants were shown two providing or eliminating advertisements for the face wash from study 3 lit from above (below). We assessed preference, likelihood to purchase, and willingness to pay in the same manner by which these were assessed in study 3. Logistic regression reveals a significant interaction based on the proximity manipulation and facewash claim ($\beta=.444, \chi^2(1)=6.981, p=.008$). As expected, results mirrored those from study 3 for all three dependent variables when participants were exposed to the proximity control. For the proximity manipulation, however, choice was at chance for the provision condition and reversed for the elimination condition. Though, we did not expect this reversal for elimination, the proximity manipulation still had the anticipated effect of disturbing typical preferences thereby exposing the role of perceptual expectations.

The present work investigates the role of lighting directionality and metaphorical interpretations of provision and elimination properties in an increasingly visual (i.e. online and mobile) marketplace (Kane and Pear 2016). We show that products that appear to be lit from above (i.e., coming) better match consumers’ expectations for products that provide benefits (i.e., coming), but products lit from below (i.e., going) better match consumers’ expectations for products that eliminate issues (i.e., going). This subtle manipulation has critically important implications for both researchers and practitioners.

**Effects of Retail Ambient Color on Purchases of Indulgent Foods: Findings from Field and Lab Studies**

Dipayan Biswas, Courtney Szocs, and Annika Abell

**EXTENDED ABSTRACT**

Ambient sensory cues strongly influence consumer judgment and behavior. For instance, retail atmospheric elements like ambient scents (Biswas and Szocs 2019; Madzharov, Block, and Morris 2015) and ambient light (Biswas et al. 2017), among other factors, influence purchase behaviors at retail stores and at restaurants. Among all ambient sensory stimuli, ambient color is perhaps the most ubiquitous element since it is an integral aspect of any retail environment, including at stores, restaurants, and cafeterias. In that regard, we examine the effects of ambient color on children’s and adult’s food purchases. Specifically, we examine how red versus non-red ambient colors in school cafeterias can influence children’s purchases of healthy and unhealthy items. The specific focus on ambient color and its influence on food purchases is driven by both conceptual and practical considerations.

From a conceptual perspective, such a focus can enhance our understanding of cross-modal sensory influences of visual inputs associated with ambient color on food choices, which are associated with the gustatory system. This is especially important since some form of ambient color is omnipresent in almost any eating context. Moreover, prior research, which has examined cross-modal effects has mainly focused on how product related factors, rather than factors in the ambience, influence customers’ perceptions and decisions (e.g., Hoegg and Alba 2007; Krishna, Elder, and Caldeira 2010). Our focus on cross-modal effects related to ambient factors is important since managers in retail settings would potentially have more control over the ambiance than over products sold in the store or restaurant.

If ambient color does indeed influence food purchases, then consumers can potentially be nudged towards more healthful purchases through changes to the dominant color in the ambience.

We develop our hypotheses based on work in the color literature (Bagchi and Cheema 2013; Hoegg and Alba 2007; Mehta and Zhu 2009) and extend it to the cross-modal influences of visual cues on gustatory factors. In two of our field experiments, we focused on red and blue colors, consistent with prior research (Bagchi and Cheema 2013; Mehta and Zhu 2009). Specifically, red and blue are almost at the opposite ends of the color wavelength spectrum and hence, offer contrasting comparisons. In addition, extensive prior research demonstrates interesting differential effects of red versus blue colors on behaviors (Bagchi and Cheema 2013; Mehta and Zhu 2009). Building on this research stream, we propose a set of hypotheses. We test our hypotheses with the help of three field experiments at school cafeterias and a series of lab experiments.

First, a large-scale field experiment at an elementary school (study 1) showed that when the cafeteria at the school had red (vs. blue) as the dominant ambient color, the children purchased unhealthy foods to a greater extent.

We followed this up with a natural field experiment at a high school where the cafeteria was repainted. Before repainting, the cafeteria did not have red color in the ambience; after the painting, the cafeteria had a predominantly red colored ambience. The results of this study again demonstrate that red ambient color leads to a greater degree of unhealthy food purchases.

Then, study 3, a field experiment at a middle school, provides evidence for the underlying process in a field setting. Specifically, the results of this study demonstrate the mediating effects of induced arousal for the effects of ambient color on food choices. This study also shows how hunger level moderates the effects of ambient color on food choices.

We followed up the field studies with a series of lab studies. Study 4 examined the underlying process through a test of moderation. The results of a 2 (ambient color: red vs. blue) X 2 (induced arousal) on food choices showed an interaction effect whereby the effects of red (vs. blue) ambient color on preference for indulgent food options got attenuated when arousal was induced (such as through watching a movie clip). Study 5 replicated the moderating effects of study 4, using a different type of arousal manipulation. Study 6 offered empirical support for our theorizing by providing an objective physiological measure of arousal. That is, GSR (Galvanic Skin Response) measures supported our theorizing that red (vs. blue) ambient color increases arousal level.

In conclusion, the findings of this research highlight the importance of ambient color on food choices. While prior research has identified effects of several different subtle factors on choices for healthy versus unhealthy options (Dhar and Wertenbroch 2012), the present research is the first to identify the effects of ambient color on choices involving healthy versus unhealthy options. The findings of this research also add to the growing literature on sensory marketing (Krishna 2012). While prior research has examined different aspects of color, no study has examined how the presence of colors in the ambience might influence food choices. Hence, our findings have implications for cross-modal sensory influences of visual cues (i.e., color) on gustatory (i.e., food choice) outcomes. The findings of this research also contribute to the literature on effects of atmospherics and environmental factors on food choices. On the practical side, school cafeterias, restaurants, and supermarkets might be able to nudge customers (children and possibly adults) towards more healthful choices by avoiding red color in the ambience.
Hot or Cold? How Ambient Temperature Influences Calorie Consumption

EXTENDED ABSTRACT

While past research suggests that exposure to extremely low temperatures (e.g., in Antarctic expeditions where temperatures are in the -77°F to 30°F range; Milan and Rodahl 1961) over a prolonged duration (e.g., one month in Milan and Rodahl 1961; three months in Kark et al. 1948), increases calorie consumption, their findings may not be applicable to typical consumption settings, such as at a restaurant or at home where consumption frequency occurs. We extend this research by demonstrating that, even within the range of temperatures typically encountered in ambient settings (67°F to 77°F), and with much shorter exposure times (10-15 minutes) that are commensurate with experiences at restaurants when ordering food, warmer temperatures lower calorie consumption relative to cooler temperatures.

Admittedly, these moderate temperatures (67°F to 77°F) and shorter time frames (10-15 minutes) are unlikely to elicit significant changes in human physiology or energy needs, which previous suggests is critical for the effects of extreme temperatures on consumption to obtain (Westerterp-Plantenga 1999); hence, these explanations cannot account for our findings. Instead, as we show, our effects emerge because of a social factor—impression management. A large literature suggests that consumers who are more concerned about managing impressions often consume lower calories. For example, consumers eat less when their consumption is observable by others, irrespective of whether these observers engage in concurrent consumption (Herman, Roth, and Polivy 2003) or are bystanders (Conger et al. 1980; Roth, Herman, Polivy, and Pliner 2001). These effects emerge because of impression management concerns (see Herman et al. 2003 for a review). We propose that warmer (vs. cooler) ambient temperatures increase impression management concerns, which lowers calorie consumption via social density perceptions.

Although the impact of temperature on perceptions of social density has not been conclusively shown, there is some evidence to suggest that temperature and social density perceptions may be correlated. Metaphorically, loneliness is often equated with a feeling of coldness, while crowding is associated with feeling warm. For example, in a poem, aptly titled “Cold and Lonely Nights,” Connie Smith expresses her love to her beloved who she is away from. While linguistics and our lived experiences support these associations, past research also provides some empirical support. Ijzerman and Semin (2010) find that increasing physical proximity increases perceptions of ambient temperature. Likewise, Zhong and Leonardi (2008) find that, when asked to recall lonely situations, participants reported the ambient temperature to be lower. Additionally, Ijzerman and Semin (2010) find that inducing physical proximity increases perceptions of ambient temperature. Relatedly, Zhong and Leonardi (2008) find that, when asked to recall lonely situations, participants reported the ambient temperature to be lower. We argue that the opposite effect might also emerge—in warmer (vs. cooler) ambient conditions, social density may be judged to be higher (lower), which would then increase impression management concerns, thereby lowering (increasing) calorie consumption.

We investigate this phenomenon in four studies. We begin with a field study, where we observe consumption of customers during lunch at a restaurant on a warmer (77°F) and a colder day (68°F). We demonstrate that people consume less calories on the warmer day. In concert, we find that warmer temperatures also lower amount spent.

In study 2, using a consumption setting in the laboratory (Double Stuffed Oreo Cookies), we demonstrate that when ambient temperature is perceived to be higher, calorie consumption and total price decreased. Moreover, we demonstrate process via mediation—warmer perceived temperature leads to higher social density perceptions, which, in turn, increases impression management concerns, and lowers calorie consumption.

While ambient temperature was not manipulated in study 2, in our two subsequent studies, we manipulate ambient temperature in the laboratory. In study 3, we use a hypothetical restaurant lunch order scenario and demonstrate that when ambient temperature is higher, it increases perceptions of social density, which increases impression management concerns, thereby lowering calorie consumption.

In study 4 we used a moderation approach and actual consumption in the lab (M&Ms). In addition to manipulating ambient temperature, we also manipulate social density to be very high or low. We demonstrate that when social density is very high at the outset, impression management concerns are already likely to be high. In such a situation, warm temperatures are unlikely to induce further increases in impression management concerns, and therefore the effect of temperature is attenuated. However, consistent with our general thesis, higher density does indeed lower consumption relative to when density is lower. This effect, however, only emerges when consumption is visible.

Most societal exchanges occur in controlled environments. Given that temperature can be easily manipulated, our research thus provides an easily implementable prescriptive tool to control eating, and, therefore, has important managerial and public policy implications. Restaurant managers may find it more beneficial to lower temperatures, as it is likely to not only affect consumers’ bottom lines (by virtue of their calorie consumption) but may also affect firms’ bottom lines—this is because, as we show, temperature induced lower (vs. higher) calorie consumption also leads to lower (vs. higher) spending. The present research provides guidance for policy makers on how to protect and empower overweight and obese consumers, and to give them opportunities to make healthy choices. It appears that maintaining a warmer temperature at restaurants and homes may be one way to lower calorie consumption. Encouraging consumers to wear warmer clothing could be another (as this is likely to reduce the need to thermo-regulate).

Paper #4: Effective Advertising to the LGBTQ Communities: An Exploratory Study
Erica Ciszek, The University of Texas at Austin, USA
Kathrynn Pounders, The University of Texas at Austin, USA

SESSION OVERVIEW
This session investigates how marginalized consumer groups gain legitimacy through marketing and consumption, with a special focus on the LGBTQ+ community. The papers approach this question using a variety of methodologies and a diverse range of samples, including LGBTQ+ communities, allies, and marketing professionals. Understanding the legitimation of marginalized groups is of increasing importance to society in general and marketing specifically (Argo and Main 2008; Coskuner-Balli and Thompson 2013; Scaraboto and Fischer 2013; Walters and Moore 2002). As concepts of gender and sexual identity become more fluid, traditional categorizations and conceptualizations of marginalized consumers begin to erode. This demands a more nuanced understanding of these groups and how they themselves navigate these changes. More favorable representations serve as a means of facilitating inclusion and representation. This session will explore the many ways that legitimation of the LGBTQ+ community can be facilitated through marketing and consumption.

The first paper investigates how LGBTQ allies (vs. non-allies) respond to ads with either explicit or implicit signals of LGBTQ+ support, and under what conditions allies respond less favorably. The authors find that allies respond more favorably to explicit signals, in turn increasing purchase intentions and positive word of mouth intentions. This research also addresses the important literature gap on attitudes toward bisexual representation. The second paper explores the role of brand personality in how liberals and conservatives respond to same-sex couples in advertising. Results show that conservatives respond negatively to same-sex couples in ads because they view the ad as low in brand sincerity. Negative evaluations are attenuated when the ad is for an exciting brand. Archival analysis shows the benefits of LGBTQ+ representation by sincere brands. The third paper explores how same-sex couples navigate issues of legitimation in the context of same-sex weddings, which challenge traditional gender dichotomies. Depth interviews and ethnographic observation reveal that consumers cultivate new forms of cultural capital around redefining gender in this traditional space where their tastes and preferences are not recognized or legitimized. Further, consumers’ own moral judgements complicate their ability to reimagine gender enactments. Finally, the fourth paper reports in-depth interviews with LGBTQ+ advertising and communication professionals (brand managers, directors, consultants, CEOs, etc.), offering insights into best practices for LGBTQ+ advertising. Results emphasize the importance of authentic messaging through more nuanced and complex representations of sexual and gender minorities, intentional visibility efforts in light of a history of erasure, and producing universal messaging that resonates regardless of gender or sexual identity.

These papers address the challenges consumers and marketers face when attempting to legitimize marginalized consumers. Themes of more expansive inclusion and representation emerge across papers. Collectively, the papers prompt multiple questions for discussion: 1) What is the role of the marketplace in helping consumers establish legitimacy during times of societal change? 2) What can marketers do to ensure they legitimate consumers’ evolving conceptions of gender and sexuality? 3) How can marginalized consumers best advocate for change? These papers that examine legitimacy in the same context should set the stage for a productive and impactful discussion.

The Ally Effect: The Role of Implicit and Explicit Cues in Advertising Towards Marginalized Groups

EXTENDED ABSTRACT
Advertising research on marginalized groups often focuses on consumer reactions to in- and out-groups, putting forth the assertion that consumers will respond favorably to other members of their in-group, and less favorably to members of their out-group (Choi and Winterrich 2013; White and Dahl 2007). Specifically, research on marginalized groups has shown that companies risk alienating the dominant group of “mainstream” consumers with explicit and sometimes implicit signals of marginalized group identity in ads (Oakenfull and Greenlee 2005; Oakenfull, McCarthy, and Greenlee 2008; Read, van Driel, and Potter 2018). However, the mainstream is not a homogenous group of consumers, and variation in how different mainstream (i.e., not marginalized) consumers respond to those implicit or explicit signals remains unexplored.

In general, companies are increasingly incorporating imagery and symbolism from marginalized groups in their advertisements, reflecting diversity in the marketplace involving not only sexual orientation, race, cultural, and immigration background. Thus, it is imperative to understand how marketing managers can incorporate diversity in their ads and increase the visibility and inclusion of the marginalized group without creating dissonance among mainstream consumers. One particular group in the mainstream that is likely to react positively to signals associated with a marginalized group is that of allies. Allies are those consumers that have high affect towards and are supportive of the group. They exist for many marginalized groups including straight and cisgender people who support the LGBTQ+ community, white supporters of the Black Lives Matter movement, and neurotypical individuals who fight for the rights of individuals on the autism spectrum. In the present research, we address the following questions: 1) Do allies – those consumers with high affect towards the marginalized group – respond more favorably...
to ads with explicit or implicit signals? and 2) Under which conditions do allies respond less favorably to such ads?

In two experimental studies, we test whether allies, or straight consumers high in affect for the LGBTQ+ community, respond differently to LGBTQ+ advertising signals than non-allies, or those low in affect for the community. Specifically, we examine ally and non-ally consumer responses to different types of LGBTQ+ signals (studies 1 and 2) and type of company support signals (study 2), within a framework of LGBTQ+ affect, perceptions of authenticity, attitudes toward the ad, and consumer outcomes (brand WOM and purchase intentions).

Study 1 tested whether and when straight consumers respond favorably towards an implicit versus an explicit LGBTQ+ signal depending on their level of positive affect towards the LGBTQ+ community. 195 heterosexual (straight) participants (50% women; 98/195, median age = 20 years) at a large Midwestern public university participated in this study in exchange for partial course credit. The study followed a 2 (signal: explicit vs. implicit) x continuous (affect) between-subjects design. Respondents were asked to review an ad by a fictitious company which portrayed a model with the gender-neutral name and her age. A pretest showed that the model in the ad could be perceived as either part of the LGBTQ+ community or not. We manipulated type of signal as follows. In the implicit signal condition, we overlaid the logo of the brand with the flag associated with the bi+ (pronounced "bi plus") community. In contrast to the LGBTQ+ rainbow flag, this flag is less commonly known thus sending an implicit LGBTQ+ cue. In the explicit signal condition, we specifically stated that the model was bisexual. We measured LGBTQ+ affect, attitude towards the ad, purchase, and WOM intentions using existing scales. Results show that an explicit signal can be both beneficial and harmful for the brand depending on the type of consumer. Consumers who show affect towards the LGBTQ+ community, also referred to as allies, have more positive attitudes towards an ad with an explicit LGBTQ+ signal than when this signal is implicit. This change in attitudes translates into increases in purchase and WOM intentions. On the other hand, consumers who score low on LGBTQ+ affect perceive an explicit signal to be negative. We do not find any difference in perceptions based on LGBTQ+ affect when the signal is implicit.

Study 2 tested straight consumers respond favorably towards an implicit versus an explicit LGBTQ+ signal depending on how the company shows their support of the marginalized community. This study includes 307 heterosexual (straight) participants (50% women; median age = 21 year) at a large Midwestern public university who participated in this study in exchange for partial course credit. This study involves a 2 (signal explicit vs. control) x 3 (company LGBTQ+ support: Logo, Logo + Statement, Logo + CRM) between-subjects design. The LGBTQ+ support conditions included the Human Rights Campaign’s “Best Places to Work” logo, the logo and a statement of the company’s commitment to the LGBTQ+ community, and a CRM statement claiming 5% of sales would go to support the community. The same scales as study 1 were used as well as a perceived brand authenticity scale. Findings show that there are conditions under which consumers with high affect towards the marginalized group respond more favorably towards explicit signals (HRC logo condition) but also conditions under which consumers with low affect respond more favorably to explicit signals (CRM condition). The latter is an unexpected yet important finding, showing that marketers can even reach non-allies with explicit signals associated with a marginalized group.

Taken together, the present research finds that marketers can use explicit signals associated with a marginalized group without risking favorable attitudes in the mainstream. Instead, explicit signals can even bolster the attitudes of allies, especially when the support of the marginalized group is authentic. The findings from this research have important implications for the acceptance of such ads in the mainstream media, allowing marketers to target a marginalized market without losing the mainstream market, thus helping with the inclusion of these consumers in the marketplace.

Sincere, Not Sinful: The Unique Role of Brand Personality in Shaping Liberals’ and Conservatives’ Views of LGBT Ads

EXTENDED ABSTRACT

If a manager of a sincere brand hires an agency to create their next ad campaign, will the agency consider LGBTQ content to be consistent with the brand? Likewise, if they propose an ad with LGBTQ content, how will the brand manager respond? A 2015 Wells Fargo ad featured a lesbian couple who were learning sign language in anticipation of adopting a hearing-impaired girl. Some conservative consumers condemned the ad, while many others saw the ad as positive and heartwarming (Benen 2015). We argue that while Wells Fargo may be trying to communicate brand sincerity (i.e. wholesome, sentimental, family-oriented; Aaker, 1997), consumers across the political spectrum considerably differ in how they interpret brand sincerity and the intended branding message.

Conservatives are more likely to resist change, support the status quo, and embrace traditionalism, and thereby have more negative attitudes toward the LGBTQ community (Jost, Nosek, and Gosling 2008; van der Toorn et al. 2017). It also follows that they will have a more traditional view of what constitutes brand sincerity (i.e. wholesome, family-friendly, sentimental). Thus, brand sincerity may be uniquely relevant to understanding how consumers with different moral sensibilities (i.e., liberals and conservatives) evaluate brands that wade into numerous morally and politically charged domains. This unique aspect of brand sincerity could contribute to a more nuanced understanding of how consumers respond to LGBTQ representation in ads. For example, how LGBTQ representation is received in one ad may not be entirely indicative of how a viewer will react to the same representation by another brand.

Relatedly, the LGBTQ community has traditionally been excluded from traits and concepts captured by brand sincerity, such as family and wholesomeness (Kates 1999; Kille and Tse 2017). It follows that sincere brands may be particularly well positioned to positively depict the LGBTQ community and contribute to legitimizing this marginalized group. However, some marketers may be concerned about alienating some heterosexual, cisgender consumers (Oakenfull and Greenlee, 2005; Um, 2012). We find that a barrier to more sincere LGBTQ representations in ads may come from the perception among conservatives that LGBTQ representation makes a brand appear less sincere, that this representation is less suited to sincere brands (as opposed to exciting brands), and is evaluated more negatively.

A pilot study (N= 207, heterosexual) had participants view a Fanta ad with a same-sex couple. Participants then rated the extent to which the ad represented brand sincerity (down-to-earth, family-oriented, wholesome, etc.) and excitement (daring, trendy, cool, etc.). Political orientation was also measured. As predicted, conservatives rated the brand as lower on sincerity than did liberals, but if anything rated it as more exciting.

In an experimental design, Study 1 (N= 135, heterosexual) had participants view an ad that either had a same-sex (male) or opposite-sex couple. They rated i) their attitude toward the ad, ii) the extent to
which the ad reflects each of the five brand personality dimensions (sincerity, excitement, competence, sophistication, ruggedness), and iii) political orientation. The two-way interaction between ad (same-sex vs. opposite-sex couple) and political orientation was only significant for ratings of sincerity and not the other four brand personality dimensions. Conservatives saw the same-sex ad as less sincere compared to liberals, and as less sincere than the opposite-sex ad. Parallel effects were found for ad attitudes. Finally, the moderated mediation effect was significant; when the ad featured a same-sex (opposite-sex) couple, more conservative participants saw the ad as less (more) sincere, which was associated with more negative (positive) attitudes.

Study 2 (N = 379, heterosexual) built off of Study 1 by also manipulating brand personality (sincere vs. exciting). The brand personality of a travel/tourism company was manipulated using imagery and the brand’s tagline, similar to past research (Aaker et al. 2004). One of the images in the ad was either of a same-sex (female) or opposite-sex couple. Participants rated i) their attitudes toward the ad, and ii) the extent to which the couple in the ad fit the brand (actor-brand fit; e.g. “The couple in this advertisement are suited to the featured brand”; Pounders and Mabry-Flynn 2016). The three-way interaction between ad content (same-sex vs. opposite-sex couple), brand personality (sincere vs. exciting), and political orientation was significant for predicting both actor-brand fit and ad attitudes. When the brand was sincere, conservatives saw the same-sex couple as a poorer fit for the brand, and rated the ad more negatively compared to liberals, and compared to the opposite-sex ad. However, when the brand was exciting, conservatives showed no preference for the opposite sex ad over the same-sex ad, nor did their attitudes differ from liberals.

We also surveyed fifty LGBTQ participants and asked what they would like to see more of in terms of LGBTQ representation. Thirty-two percent of responses made reference to content that is captured by brand sincerity (e.g. “family-oriented ads,” “happy families,” “wholesome, non-stereotypical representations”). We also analyzed 316 ads with LGBT content by having the advertised brand rated on sincerity vs. excitement by coders, and combined this with a publicly available LGBTQ representation score (AdRespect.com). We found that ads for more sincere (vs. exciting) brands had more positive LGBTQ representation.

The current research leverages insights from work on brand personality and political ideology to gain a better understanding of how LGBTQ ads are interpreted by different consumers. Those advocating for more desirable and “real” LGBTQ representation may see sincere brands as particularly well positioned to do so, and help to legitimize the LGBTQ community by normalizing LGBTQ people are relationships. This inclusion may improve the brand’s reputation among the LGBTQ community and its allies, but may come at the cost of alienating conservative consumers. Conversely, while the inclusion of LGBT content is relatively “safe” for exciting brands from an alienation point of view, such representations may not be sufficiently meaningful, progressive, or counter-stereotypical to earn goodwill or stand out among LGBT consumers and allies.

When Consensus Is Lost: Mobilizing Capital to Establish Consumer Legitimacy

EXTENDED ABSTRACT

In the fight for consumer legitimacy, understanding the rules of the game is critical. In turn, most consumer research illuminates how consumers seek ways to better play by these rules to elevate their power and status in the marketplace (Scaraboto and Fischer 2013; Ustuner and Thompson 2012). These rules are grounded in the taken-for-granted cultural categories, and related status hierarchies, that structure our ways of being and acting in the world (Bourdieu 1998). Through socialization, individuals internalize dominant cultural categories in a structure Bourdieu terms the habitus, or the cultural unconscious (Bourdieu and Wacquant 1992). When the cultural categories we think with are called into question however (e.g., What is masculine or feminine? How should we understand sexuality? Or family?), society’s basis for evaluating what significations, depictions and enactments are considered appropriate or legitimate is disrupted. For example, current debates revolve around reassessments of strict dichotomies of gender – with some moving away from traditional ideals of femininity and masculinity to more fluid conceptions of how people express their gender. This category disruption is evidenced for example by CoverGirl’s move to hire its first CoverBoy spokesperson in 2016 (Valeriya 2016) as well as by Billy Porter’s arrival on the Oscars red carpet in Christian Siriano’s first tuxedo dress for men (Gonzales 2019). Further, the legalization of same-sex marriage points to a reconsideration of what sexual orientations are recognized as socially acceptable (Von Drehle 2013). Following these reconsiderations, there is a loss of consensus over what forms of capital are now valued within status games related to gender and sexuality.

We join an emerging body of consumer research that examines attempts to deviate from established rules (McAlexander et al. 2014; Sandikci and Ger 2010; Thompson and Ustuner 2015). In this prior work, consumers often have clear prescriptions or scripts for deviation. When cultural categories are called into question, however, consensus is lost and the script for deviating is unclear. Thus, prior work does not account for consumers’ strategies for managing these types of disruptions. More specifically, as cultural categories are disrupted, how do consumers experience a loss of consensus over what is viewed as legitimate? Further, why do some consumers mobilize capital in attempts to reestablish consensus while others do not? Why do consumers enlist particular strategies over others?

To examine how consumers experience and respond to a loss of consensus in the marketplace, we utilized depth interviews with 30 same-sex couples and ethnographic observation at wedding expos to study the consumption experiences of same-sex couples. We elected to study the wedding industry because ideas of gender and sexuality are historically embedded within the gender dichotomy of the wedding script (centered on bride/groom), and same-sex marriage directly confronts this gender dichotomy (Otnes and Pleck 2003).

Our findings establish a lack of consensus around how to appropriately signify, enact, and depict masculinity and femininity in the wedding context. Consumers whose tastes and preferences depart from traditional executions of femininity and masculinity in the wedding context are tasked with cultivating new forms of embodied cultural capital – or acquiring new skills (e.g. how to propose, fit a tux, design an engagement ring) and orientations (e.g. how to display an engagement ring to others, how to wear a tux) around how to do gender differently in the wedding space (Thompson and Ustuner 2015). Consumers who possess these forms of capital often report experiencing misalignments, defined as a disparity between what they desire and experience in the marketplace. We find evidence of this disparity as consumers describe an absence of materials, roles, and representations that recognize and legitimize their desired tastes and preferences. A disrupted consensus can also result in disorientation for consumers, meaning a sense of confusion or an unmooring around what their desires necessarily are in the marketplace. These consumers are less sure about how to express their gender in the wedding context and are still trying to understand their place in its
script. They are in the process of acquiring the necessary forms of embodied cultural capital in order to discover these desired expressions. Further, reconsidering the gendered norms and expectations inculcated through one’s primary socialization can generate complex feelings and judgements via the moral habitus through lingering illegitimitacies (Kates 2002; Thompson and Ustuner 2015) – particularly when the rules or expectations on how to “appropriately” expand upon past prescriptions are unclear.

Some, but not all, consumers mobilize capital in efforts to manage this lack of consensus in the marketplace. More specifically, we identify how consumers’ variations in moral capital and embodied cultural capital shape whether and how they engage in strategies aimed at addressing the misalignments or disorientation generated around their desired tastes and preferences. Here, moral capital – defined as (il)legitimacy around sexuality – acts as an entry card by determining whether or not consumers engage in mobilization strategies. Those who possess moral capital in their local field engage in these strategies, while those who lack this capital often resort to coping techniques detailed in prior literature (Adkins and Ozanne 2005; Crockett 2017; Henry and Caldwell 2006). Embodied cultural capital directs which strategies consumers use, as its shapes whether consumers have the knowledge or skills needed to imagine and execute their desired gender expressions in the wedding context. Those with requisite embodied cultural capital tend to confront service providers in attempts to educate them on how to better respond to their evolving gendered tastes and preferences. In contrast, consumers lacking the requisite embodied cultural capital tend to either collaborate with service providers or experiment with gender resignifications through more experiential trial and error in efforts to cultivate new forms of capital. Throughout this process of discovering and executing their desires, the moral habitus – as a foundation for moral judgments – shapes how consumers evaluate and judge their activities and aspirations in the marketplace.

Effective Advertising to the LGBTQ Communities: An Exploratory Study

EXTENDED ABSTRACT

The lack of gender diversity in the media, particularly advertising, has recently become a dominant thread in cultural and industry discourses (Kemp 2018). Additionally, although efforts in advertising have been made to incorporate content inclusive of lesbian, gay, bisexual, transgender and queer (LGBTQ) perspectives, and have been successful at times, oftentimes these representations fall short. Traditionally, many of these ads have been associated with specific (and often stereotypical) product types, such as fashion and alcohol (Tsai 2011) and tend to be predominantly featured during specific times, such as Pride Month. This is surprising, as the buying power of this market has grown over $80 billion from 2015 to an estimated $987 billion in 2017. Marketers have long justified outreach to gay and lesbian consumers because of their spending power and consumer loyalty (Oakenfull 2012). Shifting social and economic norms also suggest the importance of increasing inclusivity to this particular market. According to a 2017 Gallup Poll, 10 million Americans identify as LGBTQ, and 7.3% of millennials identify as sexual and/or gender minorities, and younger people, especially Generation Z, are less committed to traditional gender norms, embracing queer identities and seeking brands who reflect similar perspectives. While some recent ad campaigns have been successful in integrating diverse LGBTQ representations, advertising that encompasses a complex representation of sexuality and gender is lacking. Further, there is scant academic research that has focused on investigating effective advertising strategies to the LGBTQ community.

Provided the lack of extant research in the area, an exploratory study was conducted. A total of thirty-three individuals participated in semi-structured interviews between August 2017 and May 2018. Specifically, participants included national brand managers, communication directors, consultants, public relations specialists, chief executive officers, chief operating officers, directors, presidents, and vice-presidents. Interviews lasted between 45 and 90 minutes, were digitally recorded, and were transcribed in full. Textual data was analyzed using an iterative part-to-whole method of the constant comparison (Spiggle 1994).

The most prominent theme that emerged was inclusive and authentic advertising. We define inclusive authentic advertising as content that encompasses the diversity of lived experiences of LGBTQ communities. Within the discussion of inclusive authentic advertising different facets of inclusivity emerged: nuanced representations, or the depiction of complex representations of sexual and gender minorities, intentional visibility effects or the importance of concentrating integrated brand efforts within the LGBTQ community on a consistent basis, and universal messaging, or communicating content that resonates with people regardless of gender or sexual identity.

Participants discussed at length how LGBTQ audiences desire more nuanced representations that encompass their lived realities and represent the diversity of their and gender identity – and how oftentimes this is lacking in contemporary advertising. For example, participants indicated that LGBTQ audiences want content that is representative of the communities they live in, the families and relationships they have, and the professions and careers they work in. The notion of avoiding overt traditional stereotypes (e.g., effeminate gay man, masculine lesbian) emerged, but even more prominent was the importance, and often failure to depict the LGBTQ community in a complex manner that is consistent with realistic representativeness. This emerged when discussing race, family, and the lack of bisexual and transgender imagery. For example, one participant stated:

Marketers wanting to include transgender representations in advertising need to feature actual transgender individuals. Additionally, the experiences and perspectives of transgender individuals are diverse and complex, and marketing to this audience needs to reflect this heterogeneity.

Participants also spoke about the historical invisibility of bisexual and transgender perspectives in marketing, as well as a lack of authentic representations of these populations in contemporary advertising, pointing to the importance of intentional visibility efforts to combat this historical erasure. To enhance perceptions of authenticity, participants suggested brands engage with transgender populations and their allies to understand the diversity of trans experiences. This observation was noted by several participants. For example, on participant stated:

With the “B” and the “T,” we’ve not done any marketing campaigns [targeting] those communities. We talk about it with [clients]…but we’ve not had a client that says, “Hey, we have a strong business opportunity with trans women or trans men.”

Another participant explained the importance of being consistent in terms of being visible:

I want to emphasize that my job is make sure we’re out in the community all year not just during Pride. We launched a campaign to support our 30th anniversary of commitment to LGBTQ community. Additionally, to increase perceptions of inclusivity and authenticity, participants stressed the importance of communicating content that resonates with people regardless of gender or sexual identity –
employing universal messages. For example when discussing effective campaigns, one participant shared:

It has to mesh with what the brand is overall for everyone. It has to be part of that. So it’s more important to that audience but you can’t make it something different. And that’s really important. It has to have the same -- it has to be communicated pretty much in the similar tone and manner

Another shared the following sentiment when discussing a national campaign that was met with unwavering success:

We really put the whole imagery of this total family. What was important was the LGBT family was put out not as a one-off but was part of what the American family is It wasn’t separating LGBT. It was putting it out in total to the masses.

In sum, this work contributes to the literature on gender in advertising. There has been little research focus on LGTQ advertising and sexual and gender minorities, and much of this work has focused on heterosexual response to LGBTQ advertising. Additionally, there is little research in advertising literature that examines best practices to reaching LGBTQ communities. The present work addresses this gap both by identifying the importance of inclusivity and authenticity in advertising messages targeted to LGBTQ communities, and defining what inclusive and authentic advertising is to LGTQ consumers – nuanced representations, intentional visibility effects, and universal messaging.

SESSION OVERVIEW
A significant proportion of adults go online to consume various types of information daily. Four in ten Americans often get their news online (Pew Research Center 2016), while over half of consumers trust online product reviews as much as personal recommendations (BrightLocal 2018). Yet, not all information is equally diagnostic (Feldman and Lynch 1988; Herr, Kardes, and Kim 1991). Indeed, consumers process the available information in light of contextual cues that might help them determine the veracity and accuracy of the information, without having to consume all available information. For example, consumers might choose to read “recent” versus “oldest” product reviews as a way to acquire the necessary product knowledge without reading all of the existing reviews. Or they might choose to read “most read” versus “most shared” news depending on specific consumption goals. These labels act as heuristic cues that aid in the consumers’ selection and processing of information, and ultimately, their behaviors.

In this session, we answer questions regarding various cues that consumers might use to shape their behavior. In Paper #1, Dagogo-Jack and Watson demonstrate the differential effect of popular news category labels (e.g., “most shared” and “most read”) on choice and consumption of news articles, while exploring some of the contexts by which this preference might change. The authors demonstrate that most read articles are generally preferred but become less preferred when consumers hold affiliation goals. In Paper #2, Watson and Pochepstova Ghosh investigate how consumers integrate aggregate product ratings into preference decisions in light of the individual reviews and how category labels such as “most recent” or “top-rated” reviews impact this process. They demonstrate that consumers tend to place more weight on the individual reviews versus the aggregate ratings but salient review labels can attenuate this effect. While much literature in the substantive domain has focused on the average product ratings and review volumes, Paper #3 demonstrates the important role of an overlooked central tendency, ratings mode. Villanova, Chandon Ince, and Bagchi demonstrate how the modal rating plays a key role in consumer preference formation, and how it differentially influences behavior from other attributes. The authors demonstrate that the modal rating is predictive of consumers’ perceptions even when it is inconsistent with other central tendencies. Lastly, in Paper #4, Proserpio, Troncoso, and Valsesia investigate how contextual factors related to the architecture of a review platform affect consumers’ decisions to write reviews. They study the effect of management responses and find male and female reviewers react differently to the presence of management responses. Consequently, when responses are allowed (versus not), the proportion of female reviewers increases for positive and decreases for negative reviews.

With diverse methodologies (e.g., field experiments, lab experiments, secondary data sources, etc.) and multiple theoretical lenses, this session should hold widespread appeal for academics interested in consumption on the internet, and in the information era, more broadly. Taken together, these four papers collectively aim to advance the understanding of consumer behavior online, which holds significant implications for theory, consumers, and managers going forward.

The Effects of Engagement Metrics on Media Consumption: A Persuasion Knowledge Account

EXTENDED ABSTRACT
To capture consumers’ attention and, consequently, advertisers’ dollars, media outlets often conspicuously list the content people are engaging with the most. Presumably, highlighting the most popular articles can help overcome choice overload (Chernev et al. 2015; Iyengar & Lepper 2000), thereby keeping visitors engaged for longer. Typically, these lists are based on one of two engagement metrics: what others are reading or sharing. Although both metrics provide social proof (Cialdini 2009), we posit that they can have markedly different effects on media consumption. Indeed, this is consistent with prior research showing similar sources of social proof can differ in persuasiveness (John et al. 2017; Tu & Fishbach 2015).

Drawing on persuasion knowledge (PK) theory (Frisestad & Wright 1994; Campbell & Kirmani 2000), we propose that sharing can constitute a persuasion attempt and thus consumers will be more skeptical of content that many others have shared (vs. read). Accordingly, as active persuasion knowledge should cause suspicion of MS articles, “most read” (MR) designations should be more effective drivers of media consumption than “most shared” (MS). However, since sharing, but not reading, is an inherently social phenomenon, consumers should pursue MS articles when affiliation motives are active. That is, opening oneself to persuasion by consuming content that others are sharing can help satisfy affiliation motives (Cialdini & Goldstein 2004; Tam 2015). Thus, active affiliation motives should eliminate the preference for MR (vs. MS).

Study 1 examined whether people generally prefer MR to MS across both highbrow and lowbrow outlets. In Study 1a, 201 participants were given a real choice of reading the MR or MS article from The Atlantic. Importantly, here and in all subsequent studies, no other information (e.g., title, author, topic) was provided about the articles. After choosing, all participants read the same article but were led to believe it was their chosen article. 63.68% of participants chose MR, which was significantly higher than chance ($\chi^2(1, N = 201) = 15.05, p < .001$). In Study 1b, 202 participants followed the same basic procedures, but the article came from Buzzfeed. Although

Advances in Consumer Research Volume 47, ©2019
Study 2 directly manipulated PK to examine its underlying role in the preference for MR over MS. 303 participants were randomly assigned to read an article that primed PK or a control article (Campbell & Kirmani 2000). Later, they chose between reading the MR or MS article from The Atlantic, and then all read the same article. Collapsing across experimental conditions, 61.06% of participants chose MR over MS, which was higher than chance ($\chi^2(1, N = 303) = 14.82, p < .001$). Furthermore, participants in the PK (vs. control) condition chose MR more (66.89% vs. 55.26%; $\chi^2(1, N = 303) = 4.31, p = .038$).

Study 3 tested the prediction that activating affiliation goals would increase the preference for MS. 500 participants were randomly assigned to a control condition or one of four goal conditions. In the goal conditions, participants imagined having a goal of fitting in with others, gaining credible information, gaining up-to-date information, or being entertained. In the control condition, there was no prime. Participants then chose between The Guardian’s MR and MS article. Before reading the article, participants rated their expectations of the MR and MS articles on various dimensions including how much the articles will help them fit in with others, gaining credible information, gaining up-to-date information, or being entertained. In the control condition, there was no prime. Participants then chose between The Guardian’s MR and MS article. Before reading the article, participants rated their expectations of the MR and MS articles on various dimensions including how much the articles will help them fit in with others, gaining credible information, gaining up-to-date information, or being entertained. In the control condition, there was no prime. Participants then chose between The Guardian’s MR and MS article. Before reading the article, participants rated their expectations of the MR and MS articles on various dimensions including how much the articles will help them fit in with others, gaining credible information, gaining up-to-date information, or being entertained. In the control condition, there was no prime. Participants then chose between The Guardian’s MR and MS article. Before reading the article, participants rated their expectations of the MR and MS articles on various dimensions including how much the articles will help them fit in with others, gaining credible information, gaining up-to-date information, or being entertained. In these studies, we attenuated the effect by making the mode less diagnostic of the representative rating, providing more evidence for our summary representation account. Pretests revealed individuals feel the modal rating is the main target of suspicion when the website provides a warning that some of the reviews may be fake (as Yelp.com does). In 4A, participants (N=202) were assigned to a 2-mode x 2-suspicion (control, high) between-subjects design. In the high-suspicion condition, participants also saw a consumer alert noting some reviews may be unreliable. The interaction was significant, with a significant (non-significant) mode effect in the control (high-
suspicion) condition. In 4B (N=202), we replicated this interaction using individual differences in suspicion about product ratings.

Pretests also indicated the mode was seen as less typical of the distribution if it had a lower relative frequency or if it was on the edge (vs. interior) of the distribution. Participants were assigned using between-subjects designs: in 4C (N=242) to a 2-mode x 3-distribution (very-dominant, less-dominant-1, less-dominant-2), and 4D (N=164) to a 2-mode x 2-location (interior, edge). The interactions were significant, with attenuated mode effects in the less-dominant and edge conditions. Together, these studies show the mode has a weaker effect on the representative rating, and in turn evaluations, when the mode is perceived as less diagnostic.

**Study 5**

To examine the mode’s effect on choice, participants (N=211) compared two brands with two product ratings distributions. We employed 2-information (averages-only, averages+mode) x 2-price-trade-off (nole, present) between-subjects design. Participants in the averages-only (averages+mode) condition saw only the average ratings (saw both averages and distributions). We structured the choice to involve trading off between a higher mean (but lower mode) and a higher mode (but lower mean) option. In the conditions with a price-trade-off, not only did the product with the higher mode (8 vs. 6) have a lower mean (6.5 vs. 7.5), it was also priced higher ($25 vs. $20). This presented participants additionally with a trade-off with price. Choice of the lower-mean (but higher-mode) option increased when distributions were shown, regardless of whether there was a price-trade-off or not (averages-only: 2% vs. averages+mode: 49%).

Across ten studies, we demonstrate that the mode of a ratings distribution has a substantial impact on consumers’ product evaluations. We also document that the mode effect occurs because consumers use the mode to inform their summary representations of the distribution.

**Does Gender Matter? The Effect of Management Responses on the Distribution of Online Reviews**

**EXTENDED ABSTRACT**

User-generated content has gained tremendous popularity in the past two decades. Every day, users read TripAdvisor reviews to choose which hotel to stay in, Amazon reviews to decide which product to buy, or Yelp reviews to pick a restaurant to eat at. A growing literature has provided evidence that online reviews can increase sales, revenues, and product or service demand. This motivates firms to invest money and effort to monitor and manage their online reputation. A popular way of doing so is the practice of publicly responding to invest money and effort to monitor and manage their online reputation. Firms are motivated to respond to online reviews because online reviews can affect not only sales, revenues, and product or service demand, but also the valence of consumer reviews. Respondents were asked to imagine they were members of an online review platform (MyTrip.com). We manipulated management responses by stating that responses to reviews were either encouraged or not allowed on the site. Respondents were randomly assigned to read about one of two hotel stay they had, pre-tested to be either positive or negative, and were asked to report their likelihood of reviewing the hotel on MyTrip.com. We predicted likelihood to review with our 3 independent variables and found a significant 3-way interaction (F(1,812)=3.01, p=0.02). Next, we analyzed male and female reactions to management responses separately. We found male reviewers are more likely to review a hotel when management responses are allowed (M_Response=5.05 vs. M_NoResponse=5.38, F(1,812)=3.66, p<0.06), irrespective of whether they had a positive or negative stay (F(1,812)=0.95, p=0.33 and F(1,812)=0.02, p=0.88). The same analysis on female reviewers instead reveals a significant interaction (F(1,812)=11.19, p<0.01). When the hotel stay is positive, likelihood to review is higher if management responses are allowed (M_Response=6.06 vs. M_NoResponse=5.20, F(1,812)=12.68, p<0.01). When the stay is negative, on the other hand, likelihood to review does not differ (M_Response=5.12 vs. M_NoResponse=5.41, F(1,812)=1.42, p=0.23).

Study 3 (N=343) was aimed at understanding how reviewers’ motivations differ across genders. Respondents were asked to imagine they were members of an online review platform (MyTrip.com), and that they had received an email update regarding the company policy about management responses. They learned that, while the website previously did not allow management responses, responses from hotel managers would soon be encouraged. Next, respondents were asked to rate how they felt about this policy change. We find female reviewers are more excited about the possibility of directly praising managers for their good work (M_Female=5.35 vs. M_Male=4.88, F(1,341)=14.14, p<0.01) and somewhat more concerned about potential confrontations that could arise with managers if they wrote a negative review (M_Female=3.93 vs. M_Male=3.60, F(1,341)=3.35, p<0.07).
Finally, study 4 explores the possibility of gender bias in the way hotel managers respond to reviews with the Linguistic Inquiry and Word Count (LIWC) text analysis program. We processed all 962,395 responses in our TripAdvisor sample. The purpose of this analysis was to investigate whether manager responses were more critical for female than for male reviews. Results suggest that, in particular when a negative review is written by a woman, management responses tend to be less positive and more negative, to use more third-person pronouns, to be angrier, and to use more power words and more negations (all ps < .01). These results are consistent with hotel managers being more critical towards reviewers that are female when it comes to addressing negative reviews.

More Payments Leads to More Patience

Discounting a Lump-sum vs. a Payment Stream:

Paper #3: Love is Patient: People are More Willing to Wait for Things They Like
Annabelle Roberts, University of Chicago, USA
Franklin Shaddy, University of California, Los Angeles, USA
Ayelet Fishbach, University of Chicago, USA
Mosi Rosenboim, Ben-Gurion University of the Negev, Israel

SESSION OVERVIEW

Time impacts consumers’ perceptions and experiences through such factors as temporal location (i.e., whether something is in the past or future; Van Boven and Ashworth 2007), distance (Trope and Liberman 2010), and duration (Ariely and Loewenstein 2000). Additionally, consumers must often make temporal tradeoffs that test their patience for purchases, finances, or experiences (Dai and Fishbach 2013; Thaler 1981), which in turn rely on how consumers perceive time (Zauberman et al. 2009).

However, though there is much work examining how time both influences peoples’ experiences and evaluations, and how those evaluations of time relate to discounting, there are still many open questions regarding consumption experiences and time. This session assembles multiple perspectives from established researchers on time to explore theoretical and practical questions regarding the impact of time on consumers’ experiences, evaluations, and perceptions of events occurring over time. For example, how specifically does the duration of an experience change how people evaluate that experience? Do consumers discount gains more than losses in both the past and in the future? How does an evaluation of a product affect patience for acquiring that product? How does a consumer’s perception of a structure of a payment (i.e., lump-sum versus payment stream) influence the discount rate?

This session examines these questions among several others. First, Diehl, Weingarten, and Zauberman develop a new conceptualization by which, contrary to duration neglect, duration has an impact on overall evaluations of experiences indirectly through its effect on experienced peak and end. Second, Molouki, Hardisty, and Caruso test in six studies how the sign effect, by which people discount gains more than losses, applies to future but not past outcomes. This asymmetry results from greater emotional intensity differences between gains and losses for the future but less so for the past. Third, Roberts, Shaddy, and Fishbach find in seven studies how, despite the possibility that liking could lead people to be impatient, liking instead increases patience. That is, people are more willing to wait for products they like more compared to products they like less. Fourth, Malkoc, Goodman and Rosenboim examine how people perceive and discount lump sums versus payment streams (e.g., monthly paychecks). Specifically, they find people are more patient with payment streams than with lump sums because they concentrate on the first payment of the payment stream.

Altogether, these four papers speak to the conference theme of expanding wisdom by illustrating how time, which is often a scarce resource, is interwoven in multiple contexts within consumer behavior and by investigating what heuristics people use when making temporal judgments.

These four papers are all in later stages of development, having all completed at least three or more studies. This session should appeal to a variety of researchers and practitioners studying time and temporal discounting, financial decision-making, emotion, judgment and decision-making, self-control, perception, and consumer experiences. Three out of the four presenters are faculty with presentation experience, thus we expect the session to be well attended.

Duration Sensitivity of Key Moments
EXTENDED ABSTRACT

One classic finding is duration neglect. That is, when individuals provide evaluations of the pleasure or discomfort they experienced, the peak and end of the experience strongly correlate with overall retrospective evaluations, while the marginal impact of duration on evaluations becomes small when controlling for peak and end (Fredrickson and Kahneman 1993). This finding triggered multiple papers that examined moderators of duration neglect (Ariely and Loewenstein 2000; Morewedge et al. 2009).

Duration, however, may actually have a systematic indirect, multiplicative effect on evaluation by influencing how people actually experience the peak and end moments. While the impact of duration after controlling for peak and end may be small, prior literature does in fact contain some evidence of a relationship between duration and peak/end (Fredrickson and Kahneman 1993; Redelmeier and Kahneman 1996).

We propose and demonstrate that duration affects the experienced key moments (peak, end), and hence duration has a multiplicative indirect effect on evaluation through these moments. This idea is consistent with recent developments in mediation suggesting that theoretically important indirect effects may exist even in the absence of direct effects (Zhao, Lynch, and Chen 2010). It is also conceptually related to a stream of research suggesting that events that occur during a time frame may influence duration (e.g., Ahn, Liu, and Soman 2009; Zauberman et al. 2010) but instead tests the opposite causal flow: duration may affect peak and end events that occur during it.

To test this idea, we conceptually replicate Fredrickson and Kahneman’s (1993) experimental setup using aversive sound clips. In a first set of two studies, we manipulated the duration of sound clips. Participants listened to three 20-second and three 60-second patternless aversive sounds (blocks counterbalanced). Participants provided moment-to-moment ratings of their discomfort while listening to the sounds, and then rated overall evaluations of discomfort after each sound. The most extreme moment-to-moment rating became peak, and the rating at the final second became the end.

Advances in Consumer Research
Volume 47, ©2019
In these two studies, we found three key results. First, we replicate the classic duration neglect: peak and end had significant effect on overall evaluations while duration had a small, if any, direct effect.

Second, as we proposed, duration had an impact on peak/end. Specifically, longer duration led to more extreme peak and end ratings, which is consistent with escalation (Coombs and Avrunin 1977).

Third, and most importantly, we observed a significant indirect effect of duration through peak/end on evaluation, demonstrating that duration has a multiplicative influence on how people evaluate experiences. These results were observed in the six-clip (within-subject) design as well as in the first clip alone (between-subject) design. Therefore, using a design that replicates Fredrickson and Kahneman’s (1993) original duration neglect study, we find evidence for an indirect effect of duration.

In a second set of three studies that replicate the original duration neglect design, we use longer or shorter sound clips each with a single, five-second amplified peak always placed fifteen seconds before the end. This manipulation ensures that duration to the peak varies between participants to be longer or shorter, but the peak and end are objectively identical. Participants again provided moment-to-moment ratings of three shorter (20 seconds) and three longer (60 seconds) otherwise pattern-less clips (blocks counterbalanced), and provided overall discomfort evaluations following each clip.

These three studies replicate the three main aforementioned results (duration neglect, a main effect of duration on peak and end, and a significant indirect effect) for the six-clip (within-subject) and first-clip alone (between-subject), demonstrating the generalizability of the results.

Therefore, in the first five studies using the Fredrickson and Kahneman (1993) design, we find a theoretically-important indirect effect of duration on evaluation through key moments (peak, end). We next use a different design in which we elicit peak and end pain without moment-to-moment ratings to bolster the generalizability of this finding.

To validate that duration has an impact on peak and end outside of moment-to-moment ratings, we ran a study in which participants rated one of peak pain, end pain, or global evaluations directly following each clip. As in the first set of two studies, participants again listened to three shorter (20 seconds) and three longer (60 seconds) pattern-less clips (blocks counterbalanced). This time, however, participants did not make moment-to-moment ratings.

Consistent with the moment-to-moment studies, direct ratings of the peak pain, direct ratings of end pain, and ratings of discomfort in global evaluations were also more severe for longer than for shorter clips.

To validate that we could observe our indirect effect of duration on global evaluation in a design without moment-to-moment ratings, we then ran a study in which participants rated all of peak pain, end pain, and global evaluations in a counterbalanced order following listening to each clip. Participants again listened to three shorter (20 seconds) and three longer (60 seconds) pattern-less clips (blocks counterbalanced). This study replicated our three findings of interest: duration neglect, an impact of duration on peak and end, and a significant indirect effect of duration on evaluation. Overall, this design provides additional evidence of a multiplicative impact of duration on evaluation.

We further replicated the aforementioned two studies without moment-to-moment ratings for the single-peaked aversive clips. The results from the two pattern-less clip studies held again for the two single-peaked studies, further cementing the generalizability of our results. These results also held when running a tenth study with the same duration (i.e., eighty seconds) but with the peak placed earlier or later in the sequence.

Ultimately, though duration may only have a small direct effect on evaluation after controlling for peak and end, we find in ten studies with over three thousand participants that duration can exert another, multiplicative indirect effect on evaluation though peak/end. Therefore, people may not neglect duration to the extent previously thought since duration affects the perception of key experiential moments (peak, end).

The Sign Effect in Past and Future Discounting

EXTENDED ABSTRACT

Consumer decisions are guided by their memories of past products and experiences, as well as their anticipation of future events (Hershfield et al. 2011; Baucells and Belleza 2017). In general, the more distant an event is in time, the less people care about it, a phenomenon known as temporal discounting (Frederick, Loewenstein and O’Donoghue 2002; Yi, Gatchalian and Bickel 2006).

A large body of work on temporal discounting has demonstrated that people discount future gains (positive events) more than losses (negative events) for an equivalent delay, a phenomenon known as the sign effect (Bilgin and LeBoeuf 2010; Mischel, Grusec and Masters 1969; Thaler 1981). The word “sign” here refers to “+” versus “−”. For example, in a pilot study (N=200), when choosing between +$49 today or -$60 in three months, participants chose the “myopic” smaller, sooner reward 70% of the time, whereas when choosing between -$49 today or -$60 in three months, participants chose the “myopic” larger, later loss only 26% of the time, z = 6.82, p < .001.

Two prevailing accounts have been offered to explain the sign effect. The loss aversion account suggests that increased sensitivity to the magnitude of negative outcomes leads to lower discounting. In general, the perceived change in utility from a loss is larger than that from an equivalent gain (Kahneman and Tversky 1979). Therefore, losses seem more impactful, and thus are discounted less, than gains of equivalent magnitude (Baucells and Belleza 2017; Loewenstein and Prelec 1992). This possibility is supported by evidence of an inverse association between discounting of losses and activation in brain areas associated with the magnitude of negative events (Tanaka, Yamada, Yoneda, and Ohtake 2014).

The contemplation utility account suggests that the sign effect is driven by the greater emotional impact not of the negative event itself, but of waiting for it to occur. This possibility is supported by people’s preference for expediting negative experiences associated with high amounts of dread (such as electric shocks; Loewenstein 1987), reflecting minimal discounting with delay. In contrast, people do prefer to delay negative experiences that are comparatively low in anticipatory discomfort (such as losing money), reflecting higher discounting with increasing delay (Berns et al. 2006). On this account, the intervening experience of contemplating the event drives discounting, not the perceived magnitude of the event itself. Similarly, enjoyment derived from waiting for a positive event, such as a vacation, could also reduce discounting of these events (Loewenstein 1987). However, the pleasure of waiting for a good experience is often mixed with negative emotion such as impatience, and tends to be felt less strongly than the pain of waiting for a bad experience (Hardisty, Frederick, and Weber 2011), leading people to discount positive events more than negative ones.

We provide a critical test to differentiate between the loss aversion account and the contemplation utility account: we systemati-
cally compare the discounting of future outcomes to the discounting of identical past outcomes. We hold constant both the valence and perceived magnitude of outcomes and measure the extent to which discounting is driven by the intensity of emotional experience while contemplating each type of event. Building on previous research linking discounting with intensity of anticipatory emotion (as distinct from predicted experience of the outcome itself; Harris 2012), we focus on assessing the emotional quality of the intervening period between the present moment and the event’s occurrence. We extend this assessment to past events by examining the emotional intensity experienced while remembering the event (as distinct from recalled experience of the event itself). We define contemplation utility as the intensity of emotion associated with thinking about the event (either anticipating or remembering it).

In six studies using both real events (eating delicious vs gross flavored jellybeans; looking at photos of puppies vs cockroaches) and hypothetical scenarios (various financial and hedonic events) with students and MTurkers, we find that people’s tendency to discount gains more than losses emerges for future events, but is reduced or eliminated for past ones. The sign effect emerges even when future positive and negative events are equated on subjective present impact, suggesting that it is not driven by loss aversion. Furthermore, the sign effect is mediated by contemplation utility: the emotional intensity from either anticipating or remembering the event. Although contemplation utility of future positive events is lower than that of future negative events across all six studies, there is no difference between contemplation utility of past positive and negative events.

These studies also reveal that the sign effect is uniquely related to the mixed nature of the contemplation utility of future positive events. The period of delay related to an upcoming positive event is characterized by both good feelings (e.g., happiness of anticipation) and bad feelings (e.g., impatience of waiting). In contrast, the period of delay related to an upcoming negative event is mostly dominated by negative emotion, with little positive emotion. Unlike people’s experience related to future events, people’s contemplation utility for past events—whether positive or negative—was of uniform quality consistent with the event’s valence. People thus discounted past positive and negative events similarly.

Furthermore, we measure and rule out loss aversion, uncertainty, risk preferences, thought frequency, and connection to future/past self as alternative explanations. While these sometimes predict discounting (for example, we replicate the finding that greater connection to distant self leads to lower discounting, Hershfield et al. 2011), none of them explain the sign effect in the future or its reversal in the past.

**Love is Patient:**

**People are More Willing to Wait for Things They Like**

**EXTENDED ABSTRACT**

How does liking affect temporal discounting? For example, when someone really likes chocolate are they more or less likely to eat a sample of chocolate now instead of waiting to eat an entire bar later, compared to someone that likes chocolate less? One possibility is that liking yields impatience, as it is more difficult to resist the smaller-sooner option. People may be particularly tempted to receive items they like sooner because the heightened attractiveness leads to a strong visceral reaction that is hard to resist (Loewenstein 1996, 2000; Mischel, Shoda, and Rodriguez 1989).

However, in this research, we make the opposite prediction: Liking causes people to become more patient. We hypothesize that liking leads to patience because when people like something more they perceive a greater difference in subjective value between the smaller-sooner and larger-later options. Because people are more patient when the perceived values of the options are greater (Dai and Fishbach 2013), we predict liking leads to patience. We test this prediction across seven studies (N=2,262).

In Study 1 we found that liking was positively correlated with patience across a range of consumer decisions. Participants ranked both how likely they would be to wait for a larger quantity or better quality version of a product as well as how much they liked the product. For example, participants ranked how much they liked Broadway shows and how likely they would be to wait six months for front row seats to a show instead of watching it from the back row this weekend. We found positive correlations between liking and patience for larger quantity ($r=.174$, $p<.001$) and better quality ($r=.154$, $p<.001$) products.

In Studies 2a-2c we manipulated liking to causally explore its effect on patience. In Study 2a, participants selected their five favorite t-shirt designs from twelve possible options and then ranked the five t-shirts from first to fifth. We then randomly assigned participants to either a high liking or low liking condition. In the high liking condition, we selected the t-shirt ranked first and asked participants how likely they would be to wait six months for that particular t-shirt in the correct size, as opposed to receiving the same t-shirt one size too large this week. In the low liking condition, we selected the t-shirt ranked fifth and presented the same tradeoff. Participants in the high liking condition were more willing to wait for the correct size ($F(1,398)=140.47, p<.001$). We found similar results with mugs and bed comforters in Studies 2b and 2c ($r^2>.03$ for all). These results suggest that when people like a consumer product more they are more willing to wait for a better quality version of it, compared to when they like it less.

In Study 3 we examined the impact of liking on patience for larger quantities. We found that liking leads to patience not just for a better version of the target, as in Studies 2a-2c, but also for a larger amount of the target. Specifically, we presented participants with different categories of food and drink (e.g., cheese, coffee, granola bars) and asked them to identify, within each category, both their favorite type and a type they would be willing to consume, but was not their favorite. For example, within the cheese category, a participant might identify Gouda as their favorite type and cheddar as a type they would be willing to consume, but was not their favorite. We then asked participants if they would prefer a sample of the food or drink today or a whole portion of the food or drink in one month for either their favorite type (high liking condition) or the type that was not their favorite (low liking condition). For all items, participants were more willing to wait for a larger portion of their favorite item (Cramer’s $V>.15$ for all).

Study 4 tested the process underlying the effect of liking on patience. We predicted that liking leads people to perceive a greater difference in subjective value between the smaller-sooner and larger-later options, thereby increasing patience. In this study participants followed the same procedure as Study 2a and also rated two measures of subjective value: how much they would enjoy and how often they would use both the correct size and larger size t-shirts. We again found participants were more patient in the high liking condition than in the low liking condition ($F(1,384)=4.69, p<.05$) and that the difference in subjective value between the correct size and larger size t-shirts was greater in the high liking condition ($F(1,384)=8.97, p<.01$). This difference mediated the effect of liking on patience (indirect effect=$0.19$, SE=$0.07$, 95% CI=[0.06,0.34]).

Finally, in Study 5 we tested for the alternative explanation that liking leads to patience because people are savoring the experience
of waiting. In this study participants followed the same procedure as Study 2c and also rated how likely they were to pay $3 to eliminate the wait for either their first favorite (high liking condition) or fifth favorite (low liking condition) bed comforter design. While participants were again more willing to wait for the preferred size in the high liking condition than in the low liking condition ($F(1,250)=11.83, p<.01$), they were also more willing to pay to receive the preferred size sooner in the high liking condition than in the low liking condition ($F(1,250)=12.16, p<.01$). Thus, when people like an item more they are both more willing to pay to receive the better version sooner, but also more willing to wait for it.

While liking might plausibly lead to impatience, as people consider the smaller-sooner option more tempting, we find that liking actually leads to patience. These findings not only provide a new theoretical insight into intertemporal choice, but also have important implications for marketers and consumers. We find that consumers are more patient for products when they like them more, and therefore individuals struggling to wait for a product may benefit from reminding themselves why they like the product they are waiting for.

**Discounting a Lump-sum vs. a Payment Stream: More Payments leads to More Patience**

**EXTENDED ABSTRACT**

Consumers’ decisions pertaining to the future involve tradeoffs between immediate and delayed outcomes. For example, consumers decide whether they want to pay more for faster shipping, and a consumer must between buying a new OLED TV today or delaying buy a bigger TV for less in a few months. In making such decisions, consumers tend to be impatient, heavily discounting the future at time (i.e., monthly streaming services, paychecks, delaying social security benefits, etc.). In this research, we compare how consumers delay lump-sum payments to equivalent streams of payments. We demonstrate that framing the same outcome as a stream of payments (as opposed to the equivalent lump-sum payment) not only leads to more consumer patience (i.e., lower discount rates), but also decreases present bias (i.e., inconsistent discount rates). These findings identify a simple way to decrease consumer impatience and de-bias a common choice anomaly, which has important implications for financial decision-making and consumer well-being.

Study 1 was a 2(Payment Type: Lump-sum vs. 12 Monthly Payments) x 2(Time: 1 Month vs. 3 Months) within-subject design. Thus, participants responded to four scenarios. To equate the value of receiving a single lump-sum at time zero ($t_0$) and 12 monthly payments, we asked participants (80 undergraduates) what how much they would need to be paid each month for 12 months to be indifferent with a lump-sum of $1200 today. Then, in the monthly payments condition, we asked participants the least they would be willing to accept (WTA) to delay these 12 payments for one month and for three months. In the lump-sum condition, participants indicated their WTA amount for one $1200 lump-sum by one month and three months. We then asked several questions to rule out alternative explanations. We converted all values to monthly premiums to conduct analyses.

Consistent with past literature, participants were present bias: Participants required higher monthly premiums for delaying for 1 month (M=98.22) than 3 months (M=83.59; $p<.055$). We also found a main effect for payment type: participants were more patient for a stream of payments (M=71.77) compared to a lump-sum (M=110.04; $p<.01$). Importantly, we found that present bias (time) was moderated by payment type ($p<.05$): There was present bias in the traditional lump-sum condition, but not in the payment condition. Further, we found no evidence that the effects were driven by differences in regret, excitement, disappointment, risk aversion/seeking, or changes in perception of time.

Study 2 (N=485 Mturkers) was a 5(Payment Type: Lump-sum, 2 Payments every 6 months, 3 Payments every 4 months, 6 Payments every 2 months, 12 Payments every month, between) x 2(Time: 3 Months vs. 6 Months, within) mixed design. In the lump-sum condition, participants indicated their WTA to delay $1200 by 3 months and 6 months. In the payment conditions, we first elicited equivalent payments for receiving $1200 at $t_0$ if they were delivered in 2/3/6/12 monthly payments (depending on condition) and then asked their WTA to delay these payment stream for 3 and 6 months. As before, analyses using monthly premiums as the dependent measures revealed a main effect of time ($M_{3months}=116.63$ vs. $M_{6months}=104.65; p<.001$) demonstrating present bias. Replicating study 1, participants were more patient for a payment stream than the lump-sum ($M_{lump-sum}=162.28$ vs. $M_{stream}=110.64; p<.001$). Further, we also that present bias was moderated by payment type, such that lump-sum led to greater present bias compared to the payment stream conditions ($M_{lump-sum}=25.15$ vs. $M_{stream}=9.44; p<.01$) and there was less present bias as the monthly amount increased ($p<.05$).

In Study 3, we explored the process behind our effect by examining whether consumers are focusing on the first payment in a payment stream while neglecting future payments. To that end, we had a 3(Lump-sum vs. Payment Stream vs. First Payment) design, where 109 MTurkers were asked to delay payments one month. In the lump-sum condition, participants indicated their WTA to delay $600. In the payment stream condition, they indicated their WTA to delay $600 in 4 payments of $150 for the next 4 months. Finally, in the first payment condition, participants indicated their WTA to delay $150 (equivalent amount of delaying the first payment in the payment stream). We also wanted to rule out amount perceptions as an alternative account and asked participants to indicate how large the amount felt like (100-point slider scale). Once again the results showed that partisans were more patient towards the payment stream (M=99.4) than the lump-sum (M=248.95; $p<.001$). Further, the payment stream was not different than simply delaying $150 (M=72.97, $p=.46$), suggesting that participants are focusing on the first payment while neglecting future payments. We examined perceived amount as an alternative explanation and found it cannot explain these results: The lump-sum (M=70.25) and the payment stream (M=65.83) did not differ ($p=.46$), and both felt larger than the first payment amount only (M=54.44; $p's <.05$), and our effect remained significant ($p <.001$) controlling for perceived amount.

Our findings suggest that that consumers become more patient and provide more consistent preferences as the monthly amount decreases (study 2) and study 3 provides further evidence that this effect is due to consumers focusing on the first payment in a payment stream while neglecting future payments. This view of a payment stream, while myopic, has the ironic effect of making consumers more patient, which could increase their long term financial well-being.

SESSION OVERVIEW
Technological progress and data proliferation have made algorithms and Artificial Intelligence increasingly widespread. Despite reports in the literature of general algorithm aversion, these technologies are frequently used by consumers and firms to provide “wisdom” and make decisions in a wide array of consumer-relevant domains. Their rapid adoption raises several questions with important implications for markets and consumers. The papers in this session help answer the following questions: When do consumers prefer algorithms to human decision-making? How is the use of algorithms changing common consumer judgments and reactions to marketing outcomes?

The first two papers identify contextual and individual factors that influence consumers’ evaluations of algorithmic decisions. In the first paper, Dietvorst and Bharti demonstrate that consumers’ acceptance of algorithms depends on the nature of the decision environment. Five studies show that consumers are more likely to use algorithms when the inherent uncertainty in the forecasting task is low. Consumers’ algorithm aversion under high uncertainty is driven by their preference for a forecaster that they believe is more likely to make a near perfect forecast, not a forecaster that they believe will perform better on average. In the second paper, Yalcin, Klesse, and Dahl identify which consumers are more likely to value algorithmic recommendations.

Across seven studies, they find that individuals with higher (vs. lower) levels of perceived competence in the focal domain value recommendations more when they were generated by algorithms (vs. human experts). This is because individuals with higher perceived competence believe they can learn more from an algorithm than an expert, while the opposite is true for individuals with lower perceived competence. The third paper explores how consumers perceive the fairness of decisions made by algorithms versus humans. Duani, Barasch, and Morwitz examine how the use of price-setting algorithms affects consumers’ fairness perceptions and consequent choices. The results of four studies show that consumers’ reaction to price discrimination by algorithms depends on the information they use. When the basis for price discrimination violates a social norm, that violation is perceived as more fair when believed to be executed by algorithms (versus humans).

This session provides timely insight into how consumers understand and respond to decisions made by algorithms, an increasingly important topic given the proliferation of this technology in consumer-contexts. Together, these three papers identify a wide array of factors that moderate consumers’ tolerance and acceptance of algorithms and decisions made by them. This session directly addresses ACR’s call for papers that generate new knowledge on how consumers make decisions in the age of new technology, including AI. This session should be of interest to scholars working on choice and decision-making, uncertainty, recommendations, fairness, pricing, morality, and new technologies.

Consumers Underuse the Best Possible Algorithm in Inherently Uncertain Environments Because They Are Risk Seeking in the Domain of Error

EXTENDED ABSTRACT
Will consumers use self-driving cars, robot doctors, and other algorithmic decisionmakers once the technology is widely available? How well will these algorithms need to perform in order for consumers to embrace them?

In many decision domains, algorithms already outperform humans (see Ogislodttir et al., 2006; Camerer, 1981; Dawes, Faust, & Meehl, 1989; Grove et al., 2000; Kaufmann, Reips, & Wittmann, 2013; Kaufmann & Wittmann, 2016; Kuncel, Klieger, Connolly, & Ones, 2013; Meehl, 1954). However, people often fail to use algorithms, even when an algorithm is the best forecasting option available (see Arkes, Dawes, & Christensen, 1986; Dietvorst, Simmons, & Massey, 2015; Estes & Straughan, 1954; Fildes & Goodwin, 2007; Sanders & Manrodt, 2003; Vrieze & Grove, 2009). Despite providing ample evidence that algorithms often outperform human judgment and that humans sometimes underuse algorithms, it is still unclear why people underuse algorithms.

In this paper, we generate forecasting tasks and let participants choose whether they want to use the best possible algorithm in order to learn under what conditions people will fail to use any algorithm. We also identify one important factor that causes people to underuse algorithms – irreducible uncertainty (uncertainty that cannot be resolved until an outcome is realized e.g. knowing which side a coin will land on). We manipulate the amount of irreducible uncertainty in our forecasting tasks and find that people are less likely to use the optimal algorithm the more inherently uncertain a forecasting task becomes, even though the optimal algorithm is always the best performing option. We probe further and find that people exhibit this behavior because they choose the forecaster that they believe is more likely to make a near perfect forecast, not the forecaster that they believe to perform better on average. This decision strategy creates risk seeking preferences. When the amount of irreducible uncertainty in the forecasting task is high, making a near perfect forecast improbable for even the optimal algorithm, people reject any algorithm and turn instead towards more uncertain, riskier (and often worse) options like human judgment.

In all studies, we created a judgement task where judges predicted an “outcome number” that was a function of three provided “input numbers.” This setup was meant to mimic real life scenarios like assessing products or investments based on a list of attributes.
Participants completed 20 practice trials where they got feedback on each judge’s performance. In Studies 1 through 4, the two judges were the participants themselves and the best possible algorithm. In Study 5, the judges were two different algorithms. After these 20 trials, the participants decided which judge’s answer they would like to use for a future incentivized trial, where they would gain more money the closer their chosen judge was to the actual outcome.

Finally, participants reported their beliefs about each judge’s performance.

In all studies, we manipulated the irreducible uncertainty in the task between subjects to see how different levels and types of irreducible uncertainty affected participants’ choice of the algorithm. In all studies, the algorithm was the optimal algorithm for the judgment task. This algorithm used the same equation that generated the outcome number (given the three input numbers) and added the expected value of any irreducible uncertainty. Thus, the algorithm made the best possible forecasts.

In Study 1, we assigned participants to one of five conditions with increasing irreducible uncertainty. The algorithm performed substantially better than did participants in each condition (p < .001) and participants recognized that it performed better on average in each condition (p < .001); however, they chose it significantly less often the more irreducible uncertainty there was in the forecasting domain (p < .001). We found direct mechanism evidence in Studies 2 through 4. In Study 2, we replicated the results of Study 1 (p < .001) and found that participants’ beliefs about which forecaster was more likely to be near perfect mediated the effect of irreducible uncertainty on their choices (.043, .122), instead of their beliefs about which forecaster was better on average (.038, .015). In Studies 3 and 4, we manipulated the variance of the algorithm between conditions (holding average performance fixed) and found that participants were more likely to pick the algorithm when it exhibited higher variance (p < .001), consistent with risk seeking preferences. In Study 5, we found that people also gravitate towards higher variance options when they choose between two algorithms (p < .001), which suggests that these risk seeking preferences generalize beyond choices between humans and algorithms.

These results suggest that convincing consumers to use algorithms in inherently uncertain domains is not a case of waiting until technology improves and algorithms perform better than they do today—people even underuse algorithms that offer the best possible performance. To the extent that choosing between products, driving, making medical decisions, investing, forecasting consumer demand, and other types of decision-making are inherently uncertain, people may be unwilling to use algorithms to make those decisions, even if those algorithms offer the best possible performance. The impact of this refusal is substantial, as society may not be able to fully benefit from technological progress in consequential but uncertain domains until people are willing to use algorithms to make inherently uncertain predictions.

The Expert vs. the Algorithm: Consumers’ Perceived Competence Impacts Their Valuation of Product Recommendations

EXTENDED ABSTRACT

Nowadays customers receive product recommendations from humans (e.g., travel experts) and/or algorithms. Interestingly, companies utilize different strategies when it comes to explaining the source of the recommendation to their customers. Whereas some companies (e.g., Wix.com) communicate that the recommendation was generated by an algorithm, others disguise the algorithm and suggest that the recommendation stems from a human expert (e.g., Stitch Fix). This raises the question whether recommendations are valued more or less depending on the framing of its source (i.e., an algorithm or human expert). Notably, existing research shows conflicting results: whereas ample research documents that individuals are reluctant to follow algorithmic recommendations (e.g., Yeomans et al., 2019), recent work suggests that individuals rely more on algorithmic advice than human advice (Logg et al., 2019).

We intend to resolve this controversy by incorporating an important characteristic—perceived competence—of the recommendation recipient. Essentially, we put forward that as consumers’ perceived competence in a focal domain increases (vs. decreases), they value a recommendation more when it is framed to be generated by an algorithm (vs. a human expert). We argue that this variation in valuation is due to differences in the extent that individuals believe they can learn something from the recommender (algorithms vs. humans). As recommendation-recipients’ perceived competence increases they might see little added value of the advice from human experts because they believe to possess similar information and capabilities. This reasoning is built on research demonstrating that individuals with confidence in their own abilities discount expert advice (Tost et al., 2012) but seek access to information that they do not possess themselves (e.g., Budescu & Ranitila, 2000); the latter suggests that individuals with high perceived competence might value algorithmic advice more because it provides them with access to different insights (e.g., Bonaccio & Dalal 2006; Van Swol & Ludutsky 2007; Yaniv 2004a, 2004b).

Conversely, as individuals consider themselves as not knowledgeable or unskilled (i.e., low perceived competence), they might value human experts’ advice more because they lack the knowledge of basic concepts (Alba & Hutchinson, 2000) and competence that experts have.

This reasoning is in line with previous work demonstrating that patients tend to follow physicians’ recommendations rather than algorithmic advice (Promberger & Baron, 2006). Moreover, the same literature indicates that people tend to use advice coming from other humans when the task is perceived to be difficult (e.g., Gino & Moore, 2007). As human-based (vs. algorithmic) recommendation processes are perceived to be as easier to understand (Yeomans et al., 2019), we argue that consumers might value human-based (algorithmic) recommendations more as their perceived competence decreases.

Seven studies test our predictions. In each study, participants received a concrete context (e.g., planning a trip), and were told about a service that provides personalized recommendations. We utilized five different domains (i.e., travel routes, jokes, brand names, coffee, Halloween costumes) to test generalizability and robustness of our effect. Depending on the condition, the service was either framed to utilize an algorithm or a human expert to generate recommendations. We assessed participants’ valuation of the recommendation (e.g., willingness to pay for the service and signing-up for the service) and measured (or manipulated) participants’ perceived competence in a focal domain. Whereas a pilot study provides correlational evidence in the field that individuals with higher (vs. lower) levels of perceived competence in a domain value a service that provides algorithmic recommendations more, the remaining studies (studies 1–4) provide experimental evidence for the interaction effect. In each study, as individuals’ perceived competence in a focal domain increased, they valued a recommendation more when it was framed to be generated by an algorithm (vs. a human expert) whereas as their perceived competence decreased, they valued a recommenda-
consumers' reactions to algorithmic and human-based recommenda-
tion less when the recommendation was framed to be generated by an
class, a human expert).
Essentially, study 2 also highlights that recommendation-recipients
differ in the extent they think they can learn from algorithms vs.
humans depending on their perceived competence in a focal domain:
as their perceived competence increased, individuals believed that
they could learn more from an algorithm but as perceived compe-
tence decreased, individuals believed that they could learn more from
a human expert. Importantly, this difference in beliefs also mediated
the effect on valuation of the recommendation (PROCESS Macro,
Model 8; Hayes, 2013; ab = -.23, se = .09, CI 95% [-.41, -.07])
1.
We believe that our work provides novel insights on the impact
of algorithms on consumer judgment and decision making. First, by
keeping the recommendation constant and only varying the framing
of its source, we explore whether there are differences in perception
merely as a consequence of different sources. Most importantly, we
contribute to the literature by resolving the contradictory findings on
consumers' reactions to algorithmic and human-based recommenda-
tions (e.g., Dietvorst et al., 2015; Dzindolet et al., 2002; Logg et al.,
2019) by incorporating recommendation recipients' perceived com-
tence as an important moderating variable. Third, our research ex-
plores individuals' reaction to algorithmic advice in domains which
depend heavily on personal taste, thus adding to the recent work on
algorithms in subjective domains (e.g., Logg et al., 2019; Yeomans
et al., 2019). Additionally, our findings are relevant to companies that
provide product recommendations to their customers; they could use
customers' perceived competence as a segmentation variable to de-
cide on how to best communicate the source of a recommendation.

Unfair but Also Unbiased: How Consumer Acceptance of
Price-Setting Algorithms Depends on the Basis of Price
Discrimination

EXTENDED ABSTRACT

Price fairness is a fundamental consumer concern (Campbell,
1999; Xia, Monroe, & Cox, 2004). Consumers are averse to ineq-
uitable outcomes and avoid sellers perceived to use unfair tactics
(Bolton & Ockenfels, 2000; Fehr & Schmidt, 1999). Consumers'
fairness concerns are therefore an important input to and constraint
on managers' price setting behavior.

Importantly, rapid technological advances are now reshaping
the way managers set prices, challenging previously established no-
tions of "fair market behavior."

Specifically, data proliferation now makes it easier than ever for
managers to use dynamic or discriminatory pricing practices to tailor
prices to individual consumers (Haws & Bearden, 2006; Kannan &
Kopalle, 2001). Managers often rely on algorithms or bots to dy-
namically set targeted prices. While consumers tend to be averse to
price discrimination tactics and perceive them as unfair (Garbarino
& Lee, 2003), prior research has not explored whether their reac-
tions differ if the price setting process is determined by a non-human
algorithm versus a human.

In general, consumers may distrust algorithms more than hu-
mans because they perceive them as lacking a moral compass. Un-
like human decision makers, who are bounded by ethical and moral
considerations, nonhuman technologies have no such conscious-

1 In study 2, we also added another framing that companies use:
data scientist, a human expert but with a focus on analytical
skills. Result of our analysis revealed that the slopes of our
two human framings (i.e., human expert, data scientist) were
not significantly different (p = .26).

based limitations. Consumers may also perceive the use of price-
setting algorithms as providing firms with an unfair advantage.
However, we propose that when the pricing policy violates so-
cial norms, the same price-setting practices may seem fairer when
they are executed by algorithms versus humans. The belief that al-
gorithms have no sense of intent and cannot form judgments may
protect consumers from feeling personally targeted or discriminated
against, and may also alleviate consumers' privacy concerns. For
these reasons, we predict that consumers will hold algorithms to a
different moral standard and be more forgiving towards their biased
actions.

The first two studies provide initial support for algorithm aversion
in the context of demand-based dynamic pricing. In study 1 (N
= 441) participants imagined they had just found a winter jacket, a
rental car, or a hotel that suited their needs. They then learned that
the product’s price changes over time to meet demand, and that the
current price is 50% higher than average. In the algorithm (human)
condition, participants learned that an automated bot (sales manager)
was responsible for setting prices. Compared to participants in the
human condition, those in the algorithm condition considered the
price-setting process to be less fair (M_Human = 3.28, M_Algorithm = 2.92;
F(1,437) = 5.06, p < 0.02). They also reported being angrier at the price
setting process and predicted they would enjoy their purchase less
(Fs > 4.65, ps < 0.03). Study 2 (N = 534) replicated this algorithm
aversion in three new domains (produce, baseball tickets, or theater
tickets). Participants in the algorithm condition again considered
the price setting process to be less fair, felt angrier at the price set-
ting process, and expected to enjoy the purchase less (Fs > 5.08, ps <
0.02). They also considered the price itself to be less fair, and report-
ed lower willingness to purchase the product (Fs > 4.79, ps < 0.03).

We next examine what happens when pricing is based on infor-
mation that feels more personal, such as consumers’ demographic
characteristics. Study 3 (N = 256) tested this in a 2 (price setting
agent: human vs. bot) x 2 (basis for price discrimination: tempo-
ral vs. demographic) between-subjects design. Participants imag-
inized purchasing tickets to a local theater. In the temporal condition,
similar to the previous two studies, prices changed based on when
the consumer was making the purchase (how many days before the
show, day of the week, time of day they are shopping). In the demo-
graphic condition, prices varied based on consumers’ personal char-
acteristics (age, gender, race/ethnicity). Overall, participants found
the price, the price setting process, and the theater to be more fair in
the temporal condition than in the demographic condition (Fs > 4.59,
ps < 0.03). However, these main effects were qualified by significant
interactions (Fs > 5.68, ps < 0.02), such that participants demon-
strated algorithm aversion in the temporal condition (replicating the
findings from Studies 1 and 2), but the opposite in the demographic
condition. When prices were determined based on personal demo-
graphics, participants instead reacted more positively in the algo-

rithm than the human condition. Significant interactions and similar
patterns emerged for all other previous measures: likelihood to buy,
anger, and expected enjoyment (Fs < 5.79, ps < 0.02). Thus, although
consumers are often averse to nonhuman technologies setting prices,
they can also be more forgiving of them when price discrimination
violates social norms.

Study 4 (N = 421) had the same design as study 3 but also in-
cluded a control condition, in which participants simply learned of
the price-setting practice without any information about who was re-
sponsible for implementing them. The results replicated the findings
from study 3: participants in the demographic-based price discrimi-
nation condition considered the price and the price setting process to
be more fair when executed by a bot than a human (Fs > 3.84, ps<
0.05). They also expected to enjoy their purchase more and reported a higher willingness to buy the product in the bot condition (Fs > 7.2, ps < 0.003). Interestingly, across all these outcomes, the control condition was statistically different than the bot condition (Fs > 3.90, ps < 0.05) but not from the human condition (Fs < 0.4, ps > 0.5), suggesting that the effect is driven by an increased willingness to accept demographic-price discrimination when executed by algorithms.

These results indicate that consumers don’t always respond negatively to the use of algorithms to implement price discrimination policies. When the basis for price discrimination violates a social norm, the violation is more easily forgiven when believed to be executed by non-human technologies, which aren’t expected to know any better. These findings have practical implications for how firms communicate about their price-setting strategies: the use of algorithms may make consumers more willing to accept practices that are usually considered unfair and morally flawed. Thus, our results suggest that the same technological advances that are now making it easier for companies to implement price discrimination practices, may also act to legitimize them in the eyes of consumers.

SESSION OVERVIEW

Substantial research has documented the manner in which well-resourced adults make financial and health decisions (e.g., Lynch, 2011; Rolls et al., 2000). However, much remains unknown regarding unique consumer segments like children. This session responds to ACR 2019’s mission of becoming wise through understanding the decision-making processes of under-heard and under-represented segments; specifically, we explore the affective processes (Papers 1 and 2) and cognitive processes (Papers 3 and 4) underlying children’s financial behaviors (Papers 1, 3, and 4) and health decisions (Papers 2-4).

These four papers are all in advanced stages, conducted by scholars around the world, and studied children in developed and developing countries (the U.S., France, and Panamá). Together, these papers bridge discoveries on children of various age groups (e.g., 5-10, 6-11, and 10-12 years old), employ a diverse set of methodologies (field experiments in elementary schools in France and Panamá, naturalistic observational intervention in U.S. convenience stores, focus groups, surveys, and a longitudinal study), and reveal rich insights on how children act as consumers.

First, Echelbarger, Gelman, and Rick (Paper 1) studied the origins of spendthrift-tightwad tendencies in childhood, and importantly the developmental course of these tendencies. They found that children’s spendthrift-tightwad scores significantly predicted their spending behavior, and parents were generally tuned into their children’s feelings about money. Additionally, children retained the same affective orientation about money over time. Nicklaus, Schwartz, Lange, Cornil, and Chandon (Paper 2) explored children’s affective responses to food. Two field studies in three elementary schools in France, found that children’s pleasure forecasts of different portions for unhealthy and healthy food were relatively accurate. Furthermore, their sensory-based intervention, encouraging children to imagine the food’s taste and aroma, effectively reduced children’s chosen quantity of unhealthy foods.

Cash, McAlister, Economos, Lehnerd, Howell, and Plank (Paper 3) took a cognitive approach to explore children’s food choices. They used economic incentives (i.e., coupons of price discounts) to nudge children toward healthier options and worked with four Boston area convenience stores to introduce coupons in two nine-month phases. They found that coupons played a role in nudging children towards healthier snack purchases. Additionally, children were not using the money they saved to buy additional snacks, thus possibly saving money. Lastly, Huang and Maimaran (Paper 4) partnered with UNICEF to launch field experiments in three elementary schools in Panamá, also leveraging economic incentives (i.e., coupons of price discounts) to increase children’s healthy choices. They tracked children’s redemption of food coupons at schools’ kiosks for weeks, and uncovered that the effectiveness of economic incentives on children’s food choices depended on message complexity, age, and repeated exposure.

In concert, these four papers highlight the importance of examining the affective and cognitive processes underlying how children process information, perceive value, and make financial and health decisions. This session not only provides novel theoretical insights, but also has critical practical importance for children’s welfare and marketing practices targeting children. We believe that this session will have a broad appeal to researchers studying children across socioeconomic status, age, and nationalities.

Show Them the Money: Children’s Affective Responses to Spending and Saving Predict Their Spending Behavior

EXTENDED ABSTRACT

Different feelings linked to spending are associated with different financial outcomes in adults. For example, people who spend more than they would like (“spendthrifts”) carry more credit card debt than people who spend less than they would like (“tightwads”) (Erner et al., 2016; Rick, Cryder, & Loewenstein, 2008). Subsequent work exploring the financial implications of these orientations shows that spendthrifts and tightwads can be situationally induced to engage in different spending and saving practices, perhaps helping spenders with these different orientations to make better financial decisions (e.g., Frederick et al., 2009; Thomas, Desai, & Seenivasan, 2011). This increase in attention to spending (and saving) profiles is associated with an overall increase in attention to improving adults’ financial behaviors (e.g., Lynch, 2011).

Perhaps the most common question stemming from this research is how one becomes a tightwad or spendthrift in the first place. Surprisingly, little is known regarding the origins of spendthrift-tightwad tendencies in childhood. Instead, existing work with children tends to describe children’s understanding of concrete aspects of everyday monetary behaviors (e.g., saving, allowance) and parental socialization regarding these behaviors (e.g., Ashby, Schoon, & Webley, 2011; Berti & Bombi, 1988; Otto et al., 2006; Webley,
An important but less explored issue is how attitudes around spending and saving develop, how they relate to parental attitudes, and how they change over time. Given the financial and hedonic implications of these orientations, it is imperative that we study their origins and developmental course.

Recently, Smith and colleagues adapted the adult Spendthrift-Tightwad Scale for children aged 5-10 years and found that children within this age range can accurately report on their feelings about spending and saving, and that these feelings predict spending behavior above and beyond how much they like items offered for purchase (Smith et al., 2018). Though novel, this work was just a first step in assessing children’s affective responses to spending (and saving) money.

In the present study, 207 children 5-10 years (M=8.00 years; SD=1.69 years; 103 boys) and their parents completed surveys evaluating their affective responses to spending and saving. Children completed the 7-item child-adapted Spendthrift-Tightwad (ST-TW) Scale (based on the Berkeley Puppet Interview; Measelle et al., 1998). Sample items included forced-choices between: I like saving money vs. I like buying new things; I think carefully before spending my money vs. I buy things without thinking too much. Parents completed the adult version of the Spendthrift-Tightwad Scale for themselves (possible range: 4-26) and the child-adapted version of the scale for their child (possible range: 0-7). For both scales, higher scores indicated more spendthrift tendencies. At the conclusion of the study, children received $2.00 in quarters, any of which they could save or spend in a small lab “store” that included various toys available for purchase.

Responses to the child-adapted scale were summed for children (M=2.01; SD=1.42) and adults (M=3.40; SD=1.79). Parent responses to the adult scale for themselves were also summed (M=14.38, SD=4.11). As it has been observed in adults, the overall distribution of child-reported scores was heavily skewed towards “tightwadism.” We first tested bivariate associations between child-reported ST-TW scores and: child age, parent-reported ST-TW scores for themselves, parent-reported ST-TW scores for their child, and money spent in the store. Child-reported ST-TW scores were positively associated with child ST-TW scores as reported by parents (.31, p<.001) and with money spent in the store (.18, p=.008). That is, children who saw themselves as more “spendthrift” were reported as such by their parents via the child ST-TW Scale, and more “spendthrift” children themselves as more “spendthrift” were reported as such by their parents via the child ST-TW Scale, and more “spendthrift” children.

We provided parents with a picture book designed to generate such discussion. We discuss also the relation between children’s orientations and the discussions they have with their parents about money-related topics. Ultimately, results from this line of work may inform efforts to promote better financial health across the lifespan.

Use of Sensory Food Imagery to Drive Children to Choose Smaller Portions of Healthy and Unhealthy Snacks

EXTENDED ABSTRACT

Childhood obesity, despite a recent stabilization, still concerned 14.5% of 3-14 years-old French children in 2007 (Peneau et al., 2009). Obesity could account for 2-7% of health costs in France, and childhood obesity could cost up to $19,000 per child’s lifetime (Finkelstein et al., 2014). Both the qualitative and the quantitative components of eating behavior (i.e. “what” and “how much” is eaten) strongly determine the children’s nutritional status, which may be a risk for their present and future health, as sub-optimal behaviors may lead to energy imbalance, and ultimately overweight and obesity. Thus, it is critical to consider the potential levers to shape children’s eating behavior. Research along this line can guide population-level interventions for children and their parents, provide critical implications for public health policies, beyond traditional health-based interventions that tend to produce weak effects (Wolfenden et al., 2012; Rekhy & McConchie, 2014).

Just like adults, children are heavily influenced by portion and package size (Rolls et al., 2000). The food portions of packaged snacks have grown so much that today’s child portions are often larger than adult portions in the past (e.g., the 25-33cl “child-size” soda cup in fast-food restaurants vs. the traditional 19cl adult size bottle). Larger food packages and portion sizes and larger plates and glasses can significantly increase children’s energy intake during lunch with no compensation effect on later meals (Hetherington et al., 2018). How can we explain children’s preference for large quantities, and how can we increase the attractiveness of smaller portion sizes?

Our central hypothesis is that children (just like adults) may fail to anticipate that the sensory pleasure of eating declines with food quantity (sensory-specific satiety; Rolls et al. 1981), but being asked to recall the sensory experience of eating foods that they like (a “sensory food imagery” intervention; Papiès et al. 2012) could help them realize that smaller portions are actually best for sensory pleasure (Cornil & Chandon, 2016). First, we investigated children’s pleasure forecasts for palatable foods which can be classified as unhealthy (e.g., energy-dense, chocolate brownie) or healthy (e.g., low in energy, applesauce). Then we compared these forecasts to the actual pleasure experienced from eating different portions of these foods (on different days). Our hypothesis is that pleasure fore-
casts will be particularly biased for indulgent desserts, and less so for healthier foods which exhibit less sensory-specific satiation (Redden & Haws 2013). Then, a short intervention was developed based on sensory imagery which was administered by experimenters in school cafeterias at the afternoon snack time (~4 PM). This intervention encourages children to imagine the taste, aroma, and texture of eating palatable foods (which exhibit strong sensory-specific satiation) before their portion size choice. We tested whether sensory imagery reduces the portion sizes of the healthy or unhealthy foods chosen by children in intervention vs. control group; we also measured actual food intake, and post-meal enjoyment and satiety. The studies were approved by the relevant local IRB (CPP Est 1). They were conducted in three primary schools in Dijon, France.

The objective of the first field experiment was to measure the effect of portion size on (pre-intake) anticipated and (post-intake) experienced hunger, eating enjoyment, and healthiness ratings among 8-11 years old children for two snacks differing in energy density and healthiness perception (chocolate brownie vs applesauce), in order to investigate potential anticipation errors related to portion size. To do so, we first asked children aged 8-11 (N=83) to anticipate their post-intake eating enjoyment and residual hunger for the recommended serving size, a 50% larger portion, and a 125% larger portion of brownie or applesauce. We asked them to rate how healthy it would be to eat each portion. Over six subsequent afternoon sessions, the children ate each of these portions and then rated them on the same scales used in the first session. In each session, we also measured initial hunger. The results show that portion size strongly reduced post-intake residual hunger for both snacks. Portion size only increased post-intake eating enjoyment for brownies, not for applesauce, and this effect increased with hunger for both snacks. When the children were only slightly hungry, rather than very hungry, eating enjoyment was unrelated to portion size. Healthiness ratings were significantly higher for applesauce than for brownies and were largely unaffected by portion size. Unlike what was reported for adults in prior studies, these effects of portion sizes were fairly accurately anticipated by the children.

The objective of the second field study was to test how sensory food imagery influenced portion size choice and intake of chocolate brownie and applesauce by 8-11 years old children. In the food sensory imagery condition, children (N=84) were asked to imagine vividly the taste, smell and oro-haptic sensations of eating three hedonic foods. The children (N=87) in the control condition were asked similar questions, but for non-food related activities, such as being at the beach. After measuring initial hunger, both groups were then asked to choose between the recommended serving size, a 50% larger portion, and a 125% larger portion of either chocolate brownie or applesauce. One week later, the children went through the same procedure, but were asked about a different set of snacks. There was a significant interaction between the intervention and the type of snack (p<0.01). Compared to the control condition, sensory food imagery led children to choose 7 % less brownie on average (p<0.01). However, it had no effect on either the quantity of applesauce chosen or consumed (p=0.31 for both). Hungrier and heavier children chose and ate more, with no differences between boys and girls.

These results highlight that focusing on sensory pleasure can make children choose smaller portions size of palatable foods. The food sensory imagery intervention was especially effective at reducing the size of chosen portions among less hungry children. These results underscore the difficulty of relying on health arguments to motivate children to accept smaller snack portions. They also suggest that adults lose the ability that they had, as children, to forecast the effects of eating larger snack portions.

Using Coupons to Motivate Children to Purchase Healthy Snacks in Boston-Area Convenience Stores

EXTENDED ABSTRACT

Prior research has shown that the majority of foods purchased autonomously by children are energy-dense, nutrient-poor (EDNP) foods (Cash & McAlister, 2011; Dennisuk, et al., 2011; Engler-Stringer, Schaefer, & Ridalls, 2016; Jones et al., 2012; Lent, et al., 2015; Marshall, 2016; Sherman, et al., 2015). Few retail interventions focus on influencing the relative price of foods available to children. The primary aim of our research is to lead children away from EDNP foods and towards more healthful alternatives utilizing coupon discounts. This pilot study involved community partners and small stores in near Boston, Massachusetts.

The study involved three phases: 1) a formative research phase, 2) a baseline observation phase, and 3) the coupon intervention phase. The formative research phase involved a series of focus groups with children. Nineteen children, ages 9-15, participated in discussions about their snack food habits, shopping behaviors, and their understanding of coupons. We also pilot tested coupon designs during these sessions, and children were asked about the stores in which they shop. This helped us identify stores that might be appropriate sites for our coupon intervention.

For the observation and intervention phases, we worked with four convenience stores in the Boston area. At each of the four stores, store owners had agreed to cooperate with our research. These four stores were chosen on the basis of meeting three main criteria: 1) they were located in racially, ethnically, and economically diverse neighborhoods; 2) they were within walking distance of at least one school; and 3) they carried some products that would be considered healthy snacks (i.e., snacks that conform to USDA standards for acceptable snack items in schools, such as baked chips, whole fruit, nut mixes, etc.).

In the natural observation phase, research assistants surreptitiously recorded child purchases during before-school and after-school times. Research assistants were recording only observable data that included basic information about child shoppers (estimated grade level, gender, and whether the child was shopping alone/with a group) and their purchasing decisions (snack choice and total cost of purchase). These observations did not involve any interviews with children. The results of these observations provided baseline measurements and helped to determine which snack items were being purchased most often. Thus, they formed the foundation for the schedule of items to be discounted in the coupon intervention phase.

The coupon intervention was carried out in two rounds. In the first round, both the targeted “healthy” foods and the competing “unhealthy” foods were discounted. This first phase was relatively passive and simply involved placing coupons in the stores and monitoring sales numbers for various snack food items. In the second round, only the targeted “healthy” items were discounted and the promotion strategy was more aggressive (i.e., a character in a monkey suit approached children and pointed out the coupons). Each intervention round lasted approximately 9 months.

In each intervention round, coupons for the discounted item/amount for the week were placed on the shelf near the item and at the checkout counter. Discounts were offered on snacks that would likely be eaten in one sitting (i.e. one or two serving size quantity). Discount amounts were chosen on the basis of focus group findings and prior research (Cash & McAlister, 2011). Common discount amounts were $0.25 and $0.50. Occasionally, $1.00 discounts were also utilized.
Similar to the natural observation phase, the intervention phase involved research assistants surreptitiously recording children’s purchases. For each purchase event, we recorded the child’s estimated age range, gender, whether the child was shopping alone/with a group, whether the child paid for his/her own purchase or if another child paid, whether or not an adult was present, and whether or not an adult paid for the purchase. We also recorded all items purchased, amount paid, and whether or not a discount coupon was used.

After all intervention phases were completed, nutritional information was linked to each of the snack purchases based on the recorded brand, flavor, and package size. While drinks were not a priority for discounting in this study, the nutritional content of beverages was also included for each purchase event.

Across all stores, we recorded 2,970 purchase observations worth approximately $6,000 in total. Of the children observed, there was roughly an even gender split, and about 55% of the shoppers appeared to be in the 10-12 age range. Children purchased a range of items, but the majority of them were unhealthy snacks. Chips were the most popular, followed by candy and baked goods. The most popular snack categories held true regardless of coupon discount type.

Our results indicate that coupons may play a role in nudging children towards healthier snacking behavior. On average, children purchased slightly fewer items and spent significantly more money when targeted “healthy” items were discounted, as compared to days when there was either a competing “unhealthy” item discount or no discount. This suggests that coupons for “healthy” products may allow children to spend more on healthier snacks when the hurdle of high price is removed. Additionally, children were not compensating by using the coupon savings to purchase additional snack items (and may have actually been saving money).

A significantly greater number of targeted “healthy” items were purchased on days when these items were discounted. While sales of these items remain low, the result suggests that the use of coupons to discount healthier snacks may increase children’s interest in buying those items. When “healthy” item coupons were available in the stores, the nutritional content of purchased items was significantly improved in most cases except for total calories, calories from saturated fat, calories from sugar, and calcium. Improvements in calories from total fat, fiber, and vitamin content may be driven by increases in fruit and vegetable snack purchases during targeted discount periods.

**Children are Price Sensitive Too: Using Price Promotions to Increase Children’s Choice of Healthy Food**

**EXTENDED ABSTRACT**

Over the past three decades, the problem of overweight and obesity has gained much attention from policy makers, organizations, companies, and consumers (WHO 2005). The prevalence of infant, childhood and adolescent obesity is also rising around the world (de Onis, Blössner, & Borghi, 2010). Prior research has invested tremendous effort in testing the impact of marketing, such as food advertisements, on childhood obesity (Wright, Friestad, & Boush, 2005). However, attempts to restrict or ban advertisements of unhealthy products to children have not been proven successful (McGinnis, Gootman, & Kraak, 2006).

In this research, we aim to address the grave challenge of childhood obesity from a different angle—instead of banning or limiting marketing of unhealthy options to children, we leverage marketing tools to encourage children’s choice of healthy options. We test the effectiveness of providing economic incentives, i.e., price promotions, to increase children’s choice of healthy food. To do so, we give elementary school children coupons that present different economic incentives to purchase healthy food and measure the redemption rate of these coupons at schools’ kiosks. Even though children have a good understanding of what money means starting at the age of three (Garrison, et al., 2016), it is unclear whether they would respond to economic incentives, i.e., price promotions, like adults do.

Importantly, during elementary school years, children go through significant cognitive developments that allow them to better comprehend concepts, make abstract connections, and do computations (John, 1999). Accordingly, we hypothesize that the complexity of the message the coupon entails will determine how effective these messages are and thus children’s redemption rates across different age groups. We further predict that for younger children (ages 6-7), a simple (vs. complex) message of price promotion would be more effective, whereas for older children (ages 8-11), a complex (vs. simple) message of price promotion would conversely be more effective. In addition, as price promotions are often used repeatedly by marketers, we further test the effect of the coupons when distributed again after three weeks. Interestingly, we anticipate that during the second exposure, younger children might learn to appreciate the complex (vs. simple) message, making it the more fitting message and thus more effective. In contrast, for older children, both the simple and complex messages may become too easy and thus ineffective the second time around.

To examine these predictions, we collaborated with UNICEF to launch three field experiments at three elementary schools in Panamá. These studies were approved by the IRB in Panamá, as well as the Ministry of Education of the Republic of Panamá. In each study, we gave children coupons promoting healthy products they can redeem at their school’s kiosk. Based on interviews with the local research teams and the schools’ teachers, we selected a healthy product to promote at each school. The criteria for these products included having UNICEF’s official approval as a healthy option for children, and being considered among the popular products that children purchase at their respective kiosks. In all schools, we first distributed the coupons on a Tuesday mid-June and then again on a Tuesday mid-July. Each time, children had three days to redeem the coupons. We tracked daily sales at the kiosk before, during, and after the coupon intervention.

To cleanly manipulate message complexity and avoid cross-condition comparison, for each school we assigned only one type of coupon to each class, and randomly assigned two types of coupons across classes within each grade. Specifically, in Study 1 (N=565), the simple message promoting cereal shake clearly stated the promoted price (“A cereal shake usually costs 1 dollar. Only Tuesday to Thursday! Pay only 80 cents when you buy the cereal shake!”), while the complex message only stated the discount value and would require computation to infer the price (“A cereal shake usually costs 1 dollar. Only Tuesday to Thursday! Pay 20 cents less when you buy the cereal shake!”). We first document that distributing the coupons increased sales for the cereal shake. More importantly, logistic regression with age (young vs. old), phase (time 1 vs. time 2), coupon type (simple vs. complex), and all interactions as the independent variables revealed the predicted three-way interaction on redemption rate (Wald = 17.191, p < .001). Simple effect analysis revealed that in phase 1, young children were more likely to redeem the simple coupon than the complex coupon, but the older children were more likely to redeem the complex coupon than the simple coupon. In phase 2, young children became more likely to redeem the complex coupon compared to simple coupon, whereas older children were equally unlikely to redeem the simple and complex coupons. In all
studies, analyzing the data at the grade level, instead of collapsing to two age groups, revealed similar results.

Study 2 (N=1219) used a similar complexity manipulation as Study 1, but promoted the natural fruit beverage at a different school for generalizability. Replicating Study 1, distributing the coupons had an immediate impact on sales. The logistic regression revealed again the hypothesized three-way interaction (Wald = 25.892, \( p < .001 \)), and the predicted age differences from time 1 to time 2.

Study 3 (N=633) promoted the natural fruit beverage at yet another school, and used a different complexity manipulation: the simple message clearly stated the promoted price, whereas the complex message required children to make connections between two products of different sizes to infer the price. Replicating previous studies, distributing the coupons had an immediate impact on sales. The logistic regression revealed again the hypothesized three-way interaction (\( \text{Wald} = 31.464, \ p < .001 \)), and the predicted age differences from time 1 to time 2.

Rather than preventing marketing to children altogether, we find that using age-appropriate incentive messages can prompt children to make healthier choices. Of note, our interventions are more subtle than explicit persuasion attempts that can potentially backfire (Maimaran & Fishbach, 2014; Robinson et al., 2007). Our findings have important theoretical implications for children’s perception of value, and managerial implications to improve their health.

SESSION OVERVIEW

From a standard economic perspective, one should make a purchase if the benefit a good provides exceeds its cost. However, past literature has documented that pain of paying, or the negative affective response to parting with one’s money, may interfere with this utility maximization. (Knutson at al. 2007; Prelec and Loewenstein 1998). To date, research in this area has primarily explored how the payment mechanism influences pain of paying. For example, people experience more pain paying with cash versus credit card (Raghurib and Srivastava 2008, Shah et al. 2015; Prelec and Simester 2001), after versus before consumption (Prelec and Loewenstein 1998), or per use versus as a lump sum (Soman and Gourville 2001). However, this session proposes that drivers of pain of paying are much richer than the payment mechanism. Further, pain of paying can have surprising and important effects on consumer preferences.

The current session seeks to address two fundamental questions: what factors, beyond payment mechanism, contribute to the pain of paying? What are potential downstream consequences on consumer choice? Using a broad range of methodologies including qualitative analysis and experimental design conducted in the lab, field, and online, these four papers cohesively explore the nuanced drivers of pain of paying, and their resulting effects on choice and consumer behavior.

The first two papers explore key drivers of pain of paying. In paper 1, Pomerance examines the impact of control on pain of paying. Interestingly, he finds that this sense of control is fundamental for decreasing pain of paying, even for irresponsible decisions. In paper 2, Friedman, Hauser and Dhar propose that goods may vary in how painful they are to purchase, independent of payment mechanism, and identify goods that are high in pain of paying.

We next explore the downstream consequences on preferences. Friedman et al. find that pain of paying can lead to preference inconsistencies, in which consumers are not willing to pay as much for high pain of paying goods that they otherwise like and value more. In paper 3, Huang, Siddiqui and Ghosh examine how pain of paying affects variety seeking. They demonstrate that higher pain of paying increases consumer’s need to justify their choices, leading them to seek less variety in favor of choosing their preferred options. Finally, in paper 4, Shah, Bettman and Payne explore how pain of paying can moderate choice overload effects. The authors show that when the pain of payment is reduced, consumers do not significantly decrease buying as the choice set increases, spend less time making a decision, and report higher satisfaction ratings.

Taken together, this session cohesively bridges research in consumer behavior, financial decision-making, and public policy to identify the underpinnings of pain of paying and how it affects consumer choice.

Paying Less for What You Value More: How Pain of Paying Leads to Preference Inconsistencies

EXTENDED ABSTRACT

Imagine waking up in a hotel room on a hot night feeling extremely thirsty. Although the minibar offers a cold bottle of water for $5, many people would not be willing to purchase it, even though the value of quenching their thirst in that moment may far outweigh the monetary cost. Furthermore, those same people may have readily spent $10 for a mediocre glass of wine that evening. While traditional economics suggests that consumers should purchase an item whose consumption utility exceeds its cost, people are often unwilling to pay for goods commensurate with value. In the scenario above, many people would prefer the water to the wine if both options were offered for free, but may be less likely to purchase the water due to the greater pain of paying for water than wine.

We empirically demonstrate that goods vary in their pain of paying, or the degree to which parting with money for the item causes a negative affective response. In contrast to prior research on the pain of paying, which has mainly focused on how the mode (e.g., cash versus credit card; Raghurib and Srivastava 2008, Shah et al. 2015; Prelec and Simester 2001), coupling (e.g., pay-per-use versus one-time cost; Soman and Gourville 2001), or timing of payment (e.g., before versus after consumption; Prelec and Loewenstein 1998) influence pain of paying, we explore how certain properties of the goods themselves and their typical purchase context can also affect pain of paying. We identify goods that people find particularly painful to purchase and explore the downstream consequences that this variation in pain of paying across goods may have on preferences: specifically, consumers may pay less for goods that offer more consumption utility.

We test our hypothesis by measuring preferences among pairs of goods that differ in their pain of paying (PoP). In study 1a, participants read that they checked into a hotel. Half chose whether they would prefer to have WiFi (high PoP) or breakfast (low PoP) included for free. Half indicated their WTP for each good, and we inferred preference based on the higher price listed. We consistently find that the high PoP good is relatively more preferred in free-choice than WTP ($P_{WIFI-FREE-CHOICE}$=64% vs. $P_{WIFI-WTP}$=31%, $p<.001$).

We test this across a variety of goods, casting doubt on alternative explanations for the results. For instance, the pattern holds when market prices are specified (e.g., both the WiFi and breakfast typically cost $9.95; $P_{WIFI-FREE-CHOICE}$=67% vs. $P_{WIFI-WTP}$=24%, $p<.001$), when the high PoP good is not typically offered for free (e.g., tank of gas vs. lunch for two, $P_{GAS-FREE-CHOICE}$=64% vs. $P_{GAS-WTP}$=43%, $p=.004$), and
when the high PoP good is utilitarian rather than hedonic (O’Donnell and Evers 2018; e.g., parking vs. dessert at a restaurant, \( P_{\text{parking-free-choice}} = 79\% \) vs. \( P_{\text{parking-wtp}} = 59\% \), \( p = .003 \)).

We test this across a variety of goods, casting doubt on alternative explanations. The pattern holds when market prices are specified, making a pure transaction-utility account unlikely (e.g., both goods typically cost $14.95; \( P_{\text{wififree-choice}} = 67\% \) vs. \( P_{\text{wifiwtp}} = 24\% \), \( p < .001 \), as well as when the high PoP good is not typically free (e.g., printer ink vs. fragrance, \( P_{\text{ink-free-choice}} = 78\% \) vs. \( P_{\text{ink-wtp}} = 46\% \), \( p < .001 \), and when the high PoP good is utilitarian (O’Donnell and Evers 2018; e.g., parking vs. dessert, \( P_{\text{parking-free-choice}} = 79\% \) vs. \( P_{\text{parking-wtp}} = 59\% \), \( p = .003 \)).

The subsequent studies compare choice when goods are free to when they both cost the same price, making explanations based on task mode unlikely. For instance, participants were less likely to buy gas over lunch when both cost $23.99 than when both were offered for free (\( P_{\text{gas-free-choice}} = 66\% \) vs. \( P_{\text{gas-money}} = 51\% \), \( p = .030 \)). Study 3 extends this result to a consequential choice. Participants in the lab had a 10-minute waiting period during which they could use their phone or get a snack. Attaching a price of $1 to the decision decreased the proportion of participants choosing to use their phone (\( P_{\text{phone-free-choice}} = 55\% \) vs. \( P_{\text{phone-paid-choice}} = 44\% \), \( p = .036 \)).

Studies 4 and 5 explore the underlying process and moderators to this effect. If the difference in pain of paying across goods underlies the observed preference inconsistencies, reducing this difference should attenuate the inconsistency. Participants in study 4 chose between hotel WiFi and hotel breakfast. We varied whether they paid with their own money, with loyalty points (to reduce PoP) or for free. Paying with loyalty points increased choice of the hotel WiFi compared with paying with money (\( P_{\text{wififree-choice}} = 66\% \) vs. \( P_{\text{wifiwtp}} = 33\% \), \( p < .001 \)), bringing choice to the same level as free choice (\( P_{\text{wifi-free-choice}} = 55\% \), \( p > 1 \)). In support of our process, the difference in PoP between the WiFi and the breakfast when paying with money versus points mediated the effect on choice (95% CI[1.41, 1.54]). In further support of this process, study 5 shows that preferences are inconsistent when goods differ in their pain of paying (e.g., a guacamole appetizer vs. parking; \( P_{\text{guacamolet-free-choice}} = 66\% \) vs. \( P_{\text{guacamolet-money}} = 41\% \), \( p < .001 \)), but are consistent when the goods are similar in their pain of paying (e.g., two appetizers – guacamole vs. spinach- artichoke dip; \( P_{\text{guacamole-money}} = 50\% \) vs. \( P_{\text{guacamole-free}} = 52\% \), ns; interaction: \( p > .001 \)).

Taken together, we show that goods themselves vary in their pain of paying, and that this variation can lead consumers to pay less for goods that they otherwise prefer. Reducing the pain of paying, such as by paying with loyalty points, counteracts this preference inconsistency.

The Perception, not the Payment: How Cognitive Appraisal Influences Pain of Paying

EXTENDED ABSTRACT

After making a payment, consumers often (but do not always) attempt to reduce their subsequent spending. What determines the effect of spending on subsequent spending? Better understanding financial self-regulation (the process by which consumers adjust their financial decision making based on changes to their finances) is critical, as “either a sizeable minority or a slim majority of Americans are on thin ice financially” (Gabler 2016).

Emotions play a critical role in self-regulation generally, and they are well researched within financial decision making in the form of the pain of paying. While past work on pain of paying focuses on everything from payment-level factors that exacerbate the pain of paying (e.g. Raghunur and Srivastava 2008) to its downstream consequences (Shah et al. 2016), existing research has yet to ask how research on emotion might inform consumers’ experience of the pain of paying. Perceptions of control are a major influence on emotion (Weiner 1980), yet the relationship between control and emotion is complicated (Thompson 1981). In this work we define control as “an individual’s belief that he or she can personally predict, affect, and steer events in the present and future” (Kay et al. 2009). We predict that perceived control decreases pain of paying because control over one’s finances decreases stress (Netemeyer et al. 2017), and because people may be motivated to perceive controlled payments as less painful in order to maintain positive views of themselves as consumers. In study 1, we examine the proposed relationship absent overt manipulations of control. We ask online participants (n = 100) to look through their email receipts and/or their online bank statements to identify recent purchases. Participants listed four specific purchases, and answered questions about each purchase (perception of control over the purchase, the typicality/predictability of the purchase, how expensive the purchase felt, the price, and the pain of paying). We find a negative relationship between perceived control and pain of paying (\( \beta = -.31, t(382.43) = 4.83, p < .001 \)). We note this result holds when controlling for the purchase’s unpredictability, price, and subjective expensiveness (all \( ps < .002 \)). Additionally participants felt that the majority of purchases (81%) were under their control. Given that perceptions of control might undermine the pain of paying, the possibility that people perceive most purchases as under their control suggests one reason that consumers have trouble with financial self-regulation.

Study 2 tests whether the negative effect of perceived control on pain of paying persists across typical and atypical purchases. Existing research argues that “novelty detection... can be considered as a gateway to the emotion system” (Ellsworth and Scherer 2003). This suggests that highly typical payments may be less painful, and that the effect of control may be moderated by typicality, as consumers simply attend less to more typical stimuli, diminishing any perception-based effects. Participants (n = 200) imagined going out for dinner and a show with friends in one of four conditions (control: high/low; typicality: high/low). High control participants imagined deciding on what to order themselves, as opposed to ordering as a group. Typicality was manipulated by the items ordered and the supposed regularity with which people went out for dinner with friends (Sussman and Alter 2012) with many of the largest expenses (e.g., electronics, celebrations). We find a negative main effect of control (\( \beta = -.48, t(262.63) = 3.68, p < .001 \)), but no main effect of typicality (\( \beta = -.03, t(284.46) = .23, p = .82 \)). Further, we find a significant interaction (\( \beta = .59, t(304.88) = 2.08, p = .038 \)) such that control decreases pain among atypical stimuli (\( \beta = .18, t(290.34) = .95, p = .343 \)), but has no effect on pain among typical stimuli (\( \beta = .78, t(280.39) = 4.04, p < .001 \)).

Given the complex relationship between perceived control and emotion, in study 3 we ask whether control might increase pain of paying under certain circumstances. Specifically, we investigate whether control might force people to internalize blame after making an irresponsible purchase, thereby increasing pain. Three studies (total n = 999) adapt the paradigm in study 2, and test for an interaction between perceptions of control and whether the purchase is relatively responsible (allowing consumers to “take the credit,” decreasing pain) or relatively irresponsible (forcing consumers to “take the payment expected costs come from Satterthwaite estimates in linear mixed effects models (Kuznetsova, Brockhoff, and Christensen 2017).
90 / Pain of Paying: Antecedents and Consequences

blame,” increasing pain). All three studies utilize a 2 (control: high/low) by 2 (responsibility: high/low) factorial design using vignettes in which participants imagine going out for a night with friends. We collapse the three studies into an internal meta-analysis here for brevity and power. Combining the data, we predict pain of paying from control (high versus low), responsibility of the purchase (high versus low), their interaction, a random intercept for each study, and a random intercept by participant (one study involved two within-subject sub-scenarios). While we again find that control decreases pain of paying ($\beta = -.21$, $t(964.14) = 2.17$, $p = .030$), we notably do not find that the effect of control depends upon whether people view the spending scenario as responsible or irresponsible ($\beta = -.11$, $t(943.04) = .59$, $p = .56$).

In this research, we ask how perceptions of control over a purchase influence pain of paying. It is well known that control influences emotion, and that the relationship between control and emotion is multifaceted and complex. We find that perceived control decreases pain of paying, even in scenarios where it might be expected to do the opposite. Future work will ask whether perceiving control allows purchases to “fly under the radar,” preventing people from adjusting their spending due to its negative effects on the pain of paying.

More of the Same: Higher Pain of Payment Decreases Variety Seeking

EXTENDED ABSTRACT

Retailers offer an increasing number of payment methods to consumers to complete their purchases. The use of different payment methods influences consumers’ experienced pain of payment, the psychological discomfort of parting with money (Prelec and Loewenstein 1998). Past work shows that pain of payment can affect the quantity (Monger and Feinberg 1997; Raghunib and Srivastava 2008) and type of products purchased (Soman 2003; Thomas et al. 2011). We extend this line of work by demonstrating how pain of payment affects consumer choices when they buy multiple items within a product category, while keeping the total number of products purchased and amount spent constant.

We argue that using a more painful payment method increases consumers’ need to justify their choices and affects the amount of variety chosen. Supporting this view, prior work demonstrates that consumers who experience higher pain of payment are more likely to purchase from product categories that are easier to justify, such as essential products (Soman 2003), and avoid product categories that are harder to justify, such as vice products (Thomas et al. 2011). We argue that, in the context of choosing multiple items within one product category, one’s favorite items are easier to justify than one’s less-preferred items, as consuming less-preferred items increases post-purchase regret (Ariely and Levav 2000; Ratner, Kahn, and Kahneman 1999). Consequently, we propose that, when consumers experience high (vs. low) pain of payment, they are more likely to choose their favorite items and avoid less-preferred ones, thereby demonstrating lower variety seeking.

We find support for our argument in five studies. In a pilot study ($N = 180$) we first demonstrate that favorites are easier to justify in a multiple choice context, where consumers often over-predict satiation from repeating favorites (Galak et al. 2011). Participants imagined purchasing five tubs of ice cream using either cash or loyalty points. They saw five different flavors and were told that they can either choose five tubs of their favorite flavor (i.e., low variety seeking) or choose one tub of each of the five flavors (i.e., high variety seeking). We measured participants’ perceived ease of justification for the two options and predicted satiation rate. Participants anticipated a faster satiation rate when eating five tubs of their favorite flavor rather than five different flavors ($M_{favorite} = 3.86$, $M_{variant} = 3.09$, $F(178) = 20.06$, $p < .001$). Importantly, however, participants found it easier to justify choosing only their favorite flavor than choosing different flavors ($M_{favorite} = 5.43$, $M_{variant} = 4.91$, $F(178) = 6.58$, $p = .011$).

In Study 1 ($N = 180$) we demonstrate in a real purchase setting that higher pain of payment decreases variety seeking. We manipulated pain of payment by giving participants either two dollars in cash or in coupons to make a purchase (Shah et al. 2016). Participants purchased five energy drink powders from five flavors. Consistent with our predictions, participants who paid with cash chose a significantly lower variety of flavors than participants who used coupons ($M_{high} = 2.71$, $M_{low} = 3.15$, $t(106) = 2.25$, $p = .026$).

Studies 2 and 3 test the need for justification as the underlying process. In Study 2 ($N = 206$), participants imagined paying with cash or loyalty points and rated their need to justify choices before making a purchase. We find that participants who paid with cash (vs. loyalty points) felt higher pain of payment ($M_{cash} = 3.20$, $M_{points} = 2.31$, $t(204) = 3.62$, $p < .001$), and a higher need for justification ($M_{cash} = 4.83$, $M_{points} = 4.34$, $t(204) = 2.07$, $p = .04$). A bootstrap analysis confirmed that the effect of payment method on the need for justification was mediated by pain of payment (indirect effect) ($\beta = .17$, 95% CI (.08, .30)).

In study 3 ($N = 301$), in a real choice setting similar to study 1, we show that participants who pay with cash (versus coupons) choose fewer flavors of tea ($M_{cash} = 2.75$, $M_{coupon} = 3.14$, $F(1298) = 5.912$, $p = .016$), and this decrease in variety seeking is mediated by a greater need to justify their choices ($\beta = -.041$, 95% CI (.137, -.0001)).

An important assumption behind our predictions is that the choice set includes consumers’ favorites as well as options that are preferred less, allowing consumers to justify their choices by sticking to their favorites. By contrast, when consumers have weak preferences among the choice options and thus no favorites, pain of payment should not affect variety seeking. In the final study ($N = 602$) we manipulated pain of payment as in study 2, and asked participants to choose products from three product categories. We measured participants’ strength of preference between the options in each category. We conducted a mediated moderation analysis for each product category using pain of payment as the independent variable, pain of payment as the mediator, participants’ preference strength among the product options as the moderator, and variety of products chosen as the dependent variable. The results revealed a significant mediated moderation for each product category (Diet Coke: $\beta = .102$, 95% CI (.019, .189); Yogurt: $\beta = .128$, 95% CI (.057, .224); Instant Food: $\beta = .084$, 95% CI (.031, .148)), indicating that high pain of payment led to less variety seeking, when preference strength among the available options was relatively strong, and this effect was attenuated when consumers had weaker preferences among the available options.

Our theoretical contribution is within the literature on pain of payment. Past work has shown payment methods to affect the quantities (Monger and Feinberg 1997; Raghunib and Srivastava 2008) and type of products purchased (Soman 2003; Thomas et al. 2011). We make an important extension to these findings by showing how payment methods affect the variety of products purchased, while keeping the quantity, amount spent, and type of products constant. Our findings also have significant practical implications. We provide managers with a novel tool for managing demand, as they can increase sales of neglected products by decreasing pain of payment, or promote painful payment methods in order to entice consumers to stick to their favorite brands.
How the Pain of Payment Can Magnify and Mitigate Choice Overload Effects

EXTENDED ABSTRACT

There is no denying that consumers today have more products to choose from than ever before. At the same time, the way that individuals pay for purchases has also dramatically shifted with more and more transactions being paid for via credit/debit card or mobile payment (Greene and Schuh, 2017). Thus, while individuals are faced with choosing from a greater product assortment, which can be a potentially difficult and burdensome task, the process of spending has become more convenient and painless than ever before. In this paper, we ask whether the anticipated pain of payment associated with making a purchase from a choice set can affect the likelihood that consumers will experience choice overload effects (i.e., purchase likelihood, decision effort, decision difficulty, post-purchase satisfaction). Across field and lab experiments, we find reducing the anticipated pain of payment—either through paying by ‘plastic’ or by paying less for an item—can serve as a cue to consumers to reduce the likelihood of individuals engaging in a maximization process in order to find the best alternative and instead leads to individuals taking a more satisfying approach. This in turn leads to increased purchasing in larger choice sets, spending less time on the decision, and higher post-purchase satisfaction ratings.

In the first two field experiments, passersby were invited to purchase a black pen for $1 from a set of alternatives, either being told that they had to purchase using cash (a more painful method of purchase) or ‘plastic’. Experiment 1(N=200) had a 2 (payment form: cash, student plastic card) X 5 (number of alternatives: 2, 6, 10, 14, 18) between-subjects design. In contrast to Experiment 2, we allowed consumers to purchase as many pens as they wanted. While, there was no difference in buying likelihood in the three smaller-choice conditions between payment method, plastic-paying consumers were significantly more likely to make a purchase than cash-paying consumers in the larger choice conditions (14- and 18-choice sets). Plastic-paying individuals also bought more than one pen more frequently. Thus, in Experiment 2, we used a similar between-subjects design but restricted buying to just one pen. This restriction helped determine whether plastic-paying consumers were less susceptible to choice overload perhaps because they chose to reduce choice conflict/decision-difficulty by buying any pen that met their needs or due to the moderating effect of a less painful payment method on buying in larger choice sets. However, despite restricting individuals to just one pen, paying with plastic still led to significantly more buying in larger choice sets in comparison to when individuals paid with cash. There was no difference in small or medium choice buckets though (2- or 6-choice condition; 10-choice). Thus, once again, there was a significant interaction between payment mode and the quadratic-function of the number of alternatives.

Experiment 3 sought to answer two questions: 1) Is it indeed the pain of payment that drives differences in buying in larger choice sets and 2) From a retailer perspective (and building off previous work that shows that categorization can also moderate choice overload effects, Kahn and Wansink 2004), can the way that a larger assortment is organized/categorized influence whether payment mode always predicts greater buying in larger choice sets? Experiment 3 used a 2 (payment form: cash or plastic) X 3 (assortment structure: one-color category, two-color categories, four-color categories) between-subjects design. All participants (N=120) were given a chance to purchase one pen from a set of sixteen options for $1.00 using their own money. In the one category condition, participants were given sixteen black pens to choose between In the two-category con-
dition, the sixteen pens were organized into two-color groups containing eight black pens and eight blue pens. In the four-category condition, the sixteen pens were divided into four black/blue/green/purple color categories. After individuals made the choice whether to buy or not, they were asked follow-up questions, including how painful it was to pay $1 for the pen (adapted from Shah et al. 2016; 1-7 Likert scale: 1= Not at all painful, 7=Very Painful)? First, we found that there was no significant difference in buying as a function of payment method, when the sixteen pens were broken into two groups of eight black and blue pens each (akin to a medium size choice bucket) or four groups with four pen choices per color (akin to a small choice bucket). However, plastic-paying consumers did in fact buy more than cash-paying consumers when the sixteen pens were all black (akin to a large assortment). In addition, we found that pain of payment significantly mediated the relationship between payment form and buying in this larger assortment condition.

Experiment 4 and 5 tested the process driving these effects more deeply. In Experiment 4, we examined whether reducing the pain of payment through lowering the cost of a given item would moderate the choice overload effect using a 2 (mode of payment: cash, student ‘plastic’ card) X 3 (number of alternatives: 4, 10, 16) X 3 (price per pen: $0.25, $1.00, $2.00) between-subjects design. Regardless of payment method, reducing the price of the pen to $0.25 led to increased buying at larger choice sets, while increasing the price of the pen to $2.00 led to decreased buying. In addition, increasing the price led to a maximization process whereby individuals spent more time on the decision, tried more alternatives, and reported lower satisfaction post-purchase. A follow-up online experiment (N=400) was consistent with this maximization theory as paying with cash (versus Venmo) led to a significantly increased desire to want to search to find the best alternative.

This work contributes by better understanding factors influencing the choice overload paradigm. An increasing choice set size alone may not always produce choice overload effects but rather may be due in part to an interaction between the size of the choice set and the (anticipated) pain of payment when purchasing. Thus, pain of payment may serve as a cue of how much one should search or engage in a maximization in order to find the right alternative.

Fangyuan Chen, Hong Kong Polytechnic University, China

SESSION OVERVIEW

Prosocial behaviors are behaviors that involve self-sacrifice for the good of others or of society (Small and Cryder 2016). Consumers often engage in prosocial behaviors such as donating to nonprofits, purchasing environmentally-friendly products, and supporting cause-related marketing. Decades of work has studied what motivates consumers to behave pro-socially (Batson et al. 2007). Critical antecedents for encouraging prosocial consumption and contribution include firm’s actions, donor’s perceptions, and situational influences (e.g., Cryder, Botti, and Simonyan 2017; Darley and Latane 1968; Gneezy, Keenan, and Gneezy 2014). This session brings together papers that explore novel influencers of consumers’ prosocial behaviors from four distinct angles: (1) firm’s risky action, (2) donor’s past action, (3) the environment/nature, and (4) the machine/robot.

First, how does risk-taking by nonprofit organizations influence consumers’ willingness to support the organization? The paper by Gershon, Cryder, and Croston demonstrates that consumers are less tolerant of risk-taking by nonprofits: when a nonprofit organization chose a high risk and high expected value (vs. a safe but low expected value) fundraising option, consumers were less likely to support the nonprofit organization, because risk-taking activates paternalistic attitudes toward the firm. Interestingly, consumers do not penalize for-profit firms to the same degree for choosing the same risk, underscoring the uniqueness of prosocial industries. What can nonprofit organizations do to increase redonation? The second paper by Shehu, Clement, Winterich, and Veseli demonstrates in two field experiments and two controlled studies that giving donors feedback on their past donation use helps to convey service value, and significantly increases the number of redonation (i.e., donor retention).

Going beyond firm’s and donor’s action, how does our environment—the exposure to nature—affect prosocial consumption? The third paper by Castelo, Goode, and White shows that immersed in nature leads to self-transcendence (i.e., a sense of being connected to something greater than oneself), which decreases self-prioritization and increases prosocial consumption, e.g., choices of environmentally-friendly products. Contrasting the impact of nature on prosocial behavior, the last paper explores what happens when new technology—professional service robots—are used in prosocial missions. Huang and Chen show that consumers in general feel less inspired when they read about a robot (vs. a fellow human) carrying out a prosocial/disaster-relief act, because of the perceived lack of autonomy in robots. They document how this feeling of lower inspiration spills over to reduce consumers’ prosocial contribution for unrelated causes through two field experiments, and identify multiple ways to circumvent this negative effect (e.g., altering the description of robots’ relationship with human volunteers).

Taken together, this special session examines four critical influencers of consumers’ prosocial consumption and contribution. We study a diverse set of behaviors (donor retention, support, donation amount, and donation quantity) in the lab and the field, as well as novel mechanisms from firm perception, service value, to subjective experience such as inspiration and self-transcendence, ensuring a broad appeal for scholars and practitioners across disciplines (marketing strategy, feedback, information processing, risk, affect, self-view, motivation, decision making) and a lively discussion to encourage future research in these areas.

Risky Business: The Risk-Reward Trade-off is different for Nonprofit and For-Profit Firms

EXTENDED ABSTRACT

Consumers hold different attitudes toward nonprofit and for-profit firms. For example, consumers perceive nonprofits as warmer than for-profits, but also as less competent (Aaker, Vohs, and Mogilner 2010). Similarly, consumers believe that nonprofit hospitals are more trustworthy and humane, but also lower in quality than for-profit hospitals (Schlesinger, Mitchell, and Gray 2003). This paper investigates a novel and important difference in how consumers judge nonprofit versus for-profit firms: consumers feel paternalism toward non-profit organizations, making them judge risk-taking by nonprofits less favorably than identical risk-taking by for-profit organizations.

Five experiments find that consumers penalize a nonprofit that chooses a risky (but high expected value) option over a certain (but low expected value) option, however, they do not penalize a for-profit company to the same degree for choosing the same risk. This effect is due to the perception that nonprofits are low in agency, therefore, when nonprofits take an agentic action such as risk-taking, it evokes paternalistic attitudes and decreases consumer support.

Experiment 1 was an initial test of reactions to nonprofit risk-taking using a 2 (nonprofit/for-profit) × 2 (safe/risky) between-subjects design. In the nonprofit condition, participants read, “You regularly donate to a nonprofit called CleanWater, which provides clean, safe water to people all over the world.” Those in the for-profit condition read, “You regularly buy bottled water from a company called CleanWater.” Participants then read, “Recently, the [nonprofit/company] was deciding between two [fundraising/business]
ventures, Choice 1: [Raise/Earn] $200,000 for sure and Choice 2: 50% chance the [nonprofit/company] will [raise/earn] $1 Million and 50% chance the [nonprofit/company] will [raise/earn] $0. Participants were informed that the [nonprofit/company] chose either the safe (but low expected value) or the risky (but high expected value) option. We measured participants’ likelihood of supporting the organization in the future. Results showed a significant interaction between firm type and risk-taking (F(1,301) = 12.93, p < .001).

Despite the much higher expected value for the risky choice ($500,000 vs. $200,000), consumers showed a general decreased willingness to support firms that take risks; most importantly, this decrease was significantly and substantially greater for the nonprofit organization. (Note: A follow-up study replicated this result while using purchase intentions as the DV for both the for-profit and nonprofit.

In Experiment 2, participants imagined that they were the head of a large [nonprofit/company] and that they must decide which venture to pursue. Participants then selected either a 1) safe, but low expected value choice (raise $200,000 for sure) or 2) risky, but high expected value choice (50% chance at $1 million, 50% chance at $0). When asked to imagine that they were the head of a nonprofit (vs. for-profit), participants’ choice of the risky, but higher payoff venture decreased from 43.5% to 24.1% (g(1) = 8.43, p < .004). In other words, participants were significantly more risk-averse when acting as if they were responsible for a nonprofit compared to a for-profit firm.

Experiments 3A and 3B use the same design as Experiment 1 (though with a binary yes/no choice to support as the DV) and rule out possible alternative explanations for consumer risk-intolerance for nonprofit organizations. It is possible that consumers choose not to support nonprofits that take risks because they take particular issue with their own donation going towards a risky investment rather than towards the nonprofit’s programming (see Gneezy, Keenan, and Gneezy 2014). We therefore tested two scenarios examining the nonprofit risk-choice. In Experiment 3A, we used a 2 (nonprofit choice: safe/risky) × 2 (control/no-overhead) between-subjects design and explained to participants in the no-overhead condition that their donation would go directly to programming and not to the (risky or safe) fundraiser. In Experiment 3B, we used a 2 (nonprofit choice: safe/risky) × 2 (self- donation/other-donation) between-subjects design in which participants either made the choice to donate themselves (self-donation) or advised an anonymous individual on whether to donate to the nonprofit (other-donation; see Cryder, Botti, and Simonyan 2017). In both experiments, we found a main effect of nonprofit risk, such that participants were less likely to donate (or advise others to donate) to the risk-taking nonprofit. However, we found non- significant interactions of risk-taking and the donation treatment for both studies (ps > .20). These patterns indicate that the intolerance for risk-taking is not due to donor preferences that their own donation will not go towards a risky venture; the phenomenon persists even when participants are informed that their donation will go directly towards programming.

Experiment 4 explored process using the same design as Experiment 1 with an even higher expected value for the risky choice (safe=raise $200,000 for sure vs. risky=50% chance at $5 million, 50% chance at $0). To measure paternalistic attitudes, we collected responses to the following items: “CleanWater deserves to spend their money as they choose”, “CleanWater has the right to make their own spending choices,” and “How CleanWater spends their money is up to them,” 1=Definitely Disagree, 7=Definitely Agree (adapted from Olson, McFerran, Morales, and Dahl 2016). We also measured perceptions of warmth, competence, and morality. Results replicated the interaction from Experiments 1-3B of firm type and risk-taking on consumers choice to support the organization (Wald$F^2$(1) = 9.05, p = .003). In addition, judgments of paternalism mediated this interaction, such that participants rated a greater increase in paternalistic attitudes for the nonprofit (vs. for-profit) when they chose the risky option and this led to a greater decrease in support for the nonprofit. Further, in a test of parallel mediation, paternalistic attitudes, but not the other process items (warmth, competence, and morality) still significantly mediated the interaction.

Consumers are less tolerant of risk-taking by nonprofits than for-profits. Specifically, when nonprofits make highly agentic choices (such as taking risks), this evokes paternalistic attitudes that decrease resource allocation to the firm. Such penalties have the potential to compromise the level of innovation that nonprofits can pursue while pursuing successful fundraising campaigns.

Increasing Donor Retention with Feedback on Donation Use

EXTENDED ABSTRACT

Non-profit organizations (NPOs) face an increasing level of competition and struggle to retain donors (Kessler and Milkman 2018; Khodakarami, Petersen, and Venkatesan 2015; Ryzhov, Han, and Bradic 2016). For example, nearly a quarter of blood donors are not retained as 24.9 percent of registered blood donors in the Netherlands do not provide a second donation and statistics from the United Kingdom and United States are similar (van Dongen 2015).

Despite the high managerial relevance, many NPOs struggle to identify effective donor retention strategies. Commercial companies often rely on monetary incentives to drive repeat purchase (Datta, Foubert, and Van Heerde 2015; del Rio Olivares et al. 2018). However, NPOs do not tend to benefit from using monetary incentives because they can crowd out intrinsic motives (Benabou and Tirole 2006; Heyman and Ariely 2004). In addition, monetary incentives may dampen attitudes toward the NPO due to perceptions regarding ineffective use of funds (Gordon, Knock, and Neely 2009; Winterich and Barone 2011).

In this research, we propose and test a donor retention strategy that utilizes existing donation use information rather than relying on monetary or other extrinsic incentives.

Building on value co-creation research, we argue that giving donors feedback on their past donation use increases the perceived warm glow and value donors receive from the NPO (Vargo and Lusch 2016, 2008; McGrath 1997).

We test this retention strategy in the context of blood donation by informing donors in two field studies (N=28,222 active donors in Study 1 and N=11,166 inactive donors in Study 2) that their blood donation was used in a hospital on a certain date. These field studies compare the effectiveness of our proposed retention strategy to a best-practice appeal that merely acknowledges past donations. The results show that incorporating past donation use increases the probability to reactivate inactive donors by 11.98%, and the number of donations of active donors by 9.8% yearly. Using conservative estimates of one annual donation on average, this translates into an additional 14 donations per 1000 contacted inactive donors, and 98 donations per 1000 contacted active donors. For large organizations with a donor base of several hundreds of thousands, the effect is substantial as each blood donation may serve up to three persons.

Two subsequent controlled experiments replicate this retention effect and offer insight for the effectiveness of this appeal. Study 3 uses a one-factor, two-level between-subjects design, where re-
spondents are randomly assigned to either a past donation use or a control acknowledgment condition. Donation intentions (measured on a 7-point scale) are higher for the past donation condition (M = 4.41, SD = 2.25) compared to the control group (M = 3.79, SD = 2.34; t(224) = 2.05, p = .04). The past donation use effect is transmitted through warm glow (M = 5.02, SD = 1.58 in the past donation use versus M = 4.67, SD = 1.67; t(224) = 2.45, p = .02), and we rule out a potential mediation through victim identification. In Study 4, we show that the past donation use effect on donation intentions is transmitted through a serial mediation via warm glow and service value.

Our findings are relevant for managers and researchers alike. Our proposed strategy, which informs donors of their past donation use, can generally be easily implemented by NPOs. In fact, blood donation services in Sweden, Australia, and other countries adopted related strategies informing current donors how their latest donation is used (Stone 2015). However, the effect of this retention strategy relative to traditional donation acknowledgment strategies has not been quantified to date.

Referring to academic areas, we have three core contributions. First, our work contributes to the literature on donor retention, adding to both the nonprofit and relationship management literature. In the relationship management literature, retention can often be increased via monetary incentives (e.g., del Rio Olivares et al. 2018), which may backfire in the prosocial context (Heyman and Ariely 2004). By proposing a retention strategy that does not rely on incentives, we demonstrate a managerially relevant and cost-efficient approach to managing relationships in the nonprofit sector. In doing so, we add to recent research which shows how personalizing donation appeals by incorporating information on past donation amount or date affects redonation (e.g., Kessler and Milkman 2018; Ryzhov, Han, and Bradic 2016). We move beyond past donation amount and date and show how information on past donation use, a key piece of information relevant to existing donors’ perceptions of the NPOs service value (Sargeant 2001), increases retention.

Second, this study also adds to the literature on service value, which has not received much consideration for nonprofits (Vargo and Lusch 2008). According to McGrath (1997), nonprofit service value is what a NPO specifically does for its donors, such as appreciation and feedback. To date, research has considered the central role of service value for nonprofits from a theoretical perspective (McGrath 1997), but empirical insights are lacking. The current research addresses this gap, showing that service value plays a key role when it comes to donor retention. Nonprofits can increase the number of donors they retain by sharing past donation use information and increasing the salience of their NPOs value creation (Vargo and Lusch 2016).

Third, we show that it is not sufficient to merely acknowledge past donations; NPOs need to incorporate past donation use information in their redonation appeals to enhance their value to donors and thereby retain more donors. Thus, our findings also contribute to the literature on recognition in prosocial behavior (Winterich, Mittal, and Aquino 2013) by demonstrating that, in the redonation context, appeals pertaining to donation use are more effective than donation acknowledgment alone.

Moreover, the societal impact of successfully improving retention of blood donors is high, as the GRC notes that one blood donation can save the lives of up to three people. Thus, improving donor retention may save lives—especially for those blood types that are rare and especially in need during times of supply shortages.

The Transcendent Self: The Influence of Exposure to Nature on Self-Serving Versus Prosocial Consumption

EXTENDED ABSTRACT

We propose that exposure to nature can decrease interest in self-centered, material things and, instead, make people more other-focused and prosocial in their consumption behaviors. Past research has shown that exposure to nature has many beneficial consequences such as stress reduction (Ulrich et al. 1991), improved mood (Abraham et al. 2010), enhanced concentration (Hartig et al. 2003), and heightened attention (Berman, Jonides, and Kaplan 2008). We build on this work to propose that exposure to nature can also enhance feelings of self-transcendence—a sense of being connected to something greater than oneself. We further propose that this sense of self-transcendence subsequently decreases self-prioritization and increases prosocial behaviors.

Qualitative consumer research has explored the role of cultural narratives portraying nature as a powerful, sacred, and even divine entity, in reducing perceived barriers between oneself and the environment (Arnould and Price 1993; Canniford and Shankar 2013). In our context, we propose that exposure to nature (vs. a control) will lead to the broader sense that all of life, including but not limited to other human beings, share a common bond, are interconnected, and are part of a greater whole. This, in turn, is predicted to increase prosocial behaviors such as choosing products with ethical attributes, donating to charity rather than gaining benefits for the self, and making decisions that favor the social good over individual profit.

Study 1 asked 90 undergraduates to walk either through a natural landscape or through a more urban landscape, before measuring their state materialism (3 items; e.g., “material things are important to me”). Compared to walking in an urban area, participants who walked in nature reported lower materialism (Mnature = 4.88 vs. Murban = 5.41, t(88) = 2.26, p = .026).

Studies 2A and 2B used a recall-based manipulation in which participants wrote about a prior experience of being in nature, or about a neutral topic. In 2A, 200 MTurk participants completed an ad evaluation task in which they saw two ads for a granola bar. One ad emphasized the product’s prosocial benefits (“good for you and the environment”) and the other ad emphasized self-serving benefits (“a healthy, tasty snack”). Participants in the nature condition were more likely to prefer the option that emphasized prosocial benefits (66%) than those in the control condition (45%; χ²(1) = 8.10, p = .0004).

In Study 2B, 316 MTurk participants completed the same manipulation and a measure of self-transcendence (3 items, e.g., “I feel that on a higher level all of us share a common bond,” “All life is interconnected,” Levenson et al. 2005). Participants then read a short scenario asking them to play the role of the CEO of a fishing company, whom the government had asked to reduce his fish harvest (and profits) to benefit future generations. In the nature condition, participants were more likely to harvest less fish now in order to benefit future generations (Mnature = 582.9 vs. Mneutral = 623.6, t(306) = 2.47, p = .042).

Study 3 was a field study in which 72 participants were asked to complete a short study either before (prenatureexposure) or after (postnatureexposure) they left a hiking trail. As our primary dependent variable, we offered participants the choice between entering a draw for a selfbenefit (i.e., winning an iPad as a prize) or forgoing
the draw entry to donate to the United Way. We also measured self-transcendence as in Study 1B. Participants were significantly more likely to choose the prosocial option over the selffocused option if they made their decision after (68%) versus before nature exposure (32%, $\chi^2(1) = 8.16, p = .009$). Transcendence mediated the effect of the hiking manipulation on the prosocial choice ($\beta = .33, 95\% CI = .02–1.1$).

Study 4 demonstrates a boundary condition of the effects of nature on prosocial behavior. Specifically, because we theorize that the effects are driven by selftranscendence, the effect should be less likely to occur in contexts that make consumers feel separate and distinct from others. A research assistant approached 142 participants either before or after they completed a hike, as in Study 2. Participants were assigned to one of two additional conditions, in which they either wrote about “a time when [they] felt distinct and separate from others and the world around [them],” or did not complete any writing task. The design was therefore a 2 (nature exposure: pre vs. post-nature exposure) x 2 (selffocus: high vs. neutral). The DV was the nature exposure) x 2 (selffocus: high vs. neutral). The DV was the choice of donation vs. iPad draw, as in Study 2. A logistic regression revealed a main effect of nature exposure (pre = 0, post = 1; $\beta = 1.25, p = .021$) and a significant interaction between the two independent variables ($\beta = 1.50, p = .041$).

Participants who did not engage in the selffocus task were more likely choose the donation after (83.3%) than before nature exposure (58.8%; $\chi^2(1) = 4.48, p = .034$). When participants wrote about a time they felt separate from others, they were equally likely to donate regardless of nature exposure (after = 54.5%; before = 60.6%; $\chi^2(1) = .06, p = .803$).

A sense of feeling connected to something bigger than oneself while being immersed in nature is an intuitively appealing phenomenon. These results lend empirical support to this notion, showing that this sense of selftranscendence can occur as a result of directly experiencing or even just remembering exposure to nature. Furthermore, selftranscendence in turn increases consumers’ focus on others relative to themselves, thereby increasing prosocial behavior. These findings contribute to the literatures on selfconcept, prosocial behavior, the effects of spending time in nature. They also suggest a potentially useful marketing tool for charities and nonprofits, who may benefit from naturebased imagery and messaging in their advertising campaigns.

**When Robots Come to Our Rescue: Why Professional Service Robots Aren’t Inspiring and Can Demotivate Consumers’ Prosocial Behaviors**

**EXTENDED ABSTRACT**

Service robots refer to robots that perform services useful to the well-being of humans or equipment (ISO 8373:2012). With rapid advances in technology, the use of professional service robots in prosocial missions, such as disaster search, rescue and recovery, is becoming prevalent around the world, along with the growing news coverage of these prosocial missions (Bartneck and Forlizzi 2004; Liu and Nejat 2013; Murphy 2004). This research examines how consumers feel and react when they read about a robot carrying out a disaster relief mission that is usually performed by humans.

We propose that observing a robot conduct a disaster relief act is less inspiring to consumers than observing the same act carried out by a fellow human (H1). This lowered feeling of inspiration results from the perceived lack of autonomy in robots’ participation in the prosocial mission (i.e., the lack of ability to control over their own behaviors and act independently; Bartneck and Forlizzi 2004; Ryan and Deci 2000; Hoffman and Novak 2017). Consequently, when a robots’ autonomy is externally enhanced, the negative effect on inspiration can be mitigated (H2). More importantly, a lower feeling of inspiration will lead to a lower likelihood for consumers to support prosocial causes in subsequent, unrelated domains (H3).

Six studies provided supportive evidence for our hypotheses. Study 1 tested H1 through a 2-condition (robot vs. human) between-subjects design. Participants first read about a fictitious news report about a sudden earthquake in a small US town. Then, those in the robot (human) condition read that a robot (human) disaster response team had been sent to rescue survivors from the earthquake. We measured the extent to which participants felt inspired using scales adapted from Thrash and Elliot (2004). As predicted, participants reported a lower level of inspiration when they read about robots assist in the earthquake rescue compared to reading about fellow humans conducting the same act.

Studies 2–4 tested whether the effect was driven by the perceived lack of autonomy underlying robots’ prosocial actions (H2). We used three different ways to manipulate robot autonomy across studies. Study 2 used a 4-condition (robot-neutral, human-neutral, robot-autonomy-yes, robot-autonomy-no) between-subjects design. Participants first read a news report on a fictitious earthquake disaster. Those in the robot-neutral (human-neutral) conditions then read a seemingly unrelated article that described how, with the development of artificial intelligence technology, robots have the intelligence and learning capacities to act independently, whereas participants in the robot-autonomy-no condition conversely read about how robots are not capable of acting independently. Results from the robot-neutral and human-neutral conditions replicated Study 1 – people were less inspired by robot rescuers than by human rescuers (Mrobot = 4.03 vs. Mhuman = 5.30; F(1, 266) = 23.13, p < .001). Reading about how robots have autonomy made the robots’ prosocial action more inspiring than not reading this information (Mrobot-autonomy-yes = 4.75 vs. Mrobot-neutral = 4.03, F(1, 266) = 7.04, p = .008), whereas reading about how robots indeed lacked autonomy made no difference in the feeling of inspiration compared to the robot neutral condition (Mrobot-autonomy-no = 3.83 vs. Mrobot-neutral = 4.03, F <1).

Study 3 manipulated robot autonomy through varying the reason for the rescue. Following past research (Botti et al. 2009; Chen and Sengupta 2014), we showed that highlighting that the robots made their own decisions (vs. being instructed by humans) to conduct the disaster relief acts enhanced the perception of the robot’s autonomy, which consequently made their disaster relief acts more inspiring.

Study 4 manipulated robot autonomy through varying the description of the relationship between robots and humans (Aggarwal 2004; Yanco and Drury 2004). Participants were randomly assigned to one of the three (robot-human relationship: partner vs. subordinate vs. baseline) between-subjects design. Participants first watched a PowerPoint presentation on a recent mudslide in a US city. The PowerPoint presentation described the background of the mudslide, the damage information, and reported that teams of robots had been providing help with the rescue and recovery work. After the PowerPoint presentation, participants read further that the disaster rescue robots work with humans as teammates (partner condition), or that the robots work for humans (subordinate condition), or did not read anything about the robot-human relationship (baseline condition). As predicted, participants in the partner condition perceived greater autonomy in these robots (M = 2.76) than those in the subordinate condition (M = 1.99) or the baseline (M = 1.90), F(1, 152) > 7.80, ps < .006. As a result, participants felt more inspired in the partner condition (M = 5.26) than in the subordinate condition (M = 4.43) or
the baseline ($M = 4.62$), $F(1, 152) > 3.86$, $p < .05$. A path analysis verified that perceived autonomy mediated the effect of relationship manipulation on inspiration.

Studies 5 and 6 were built on previous studies to explore the impact of reading about robots’ prosocial actions on consumers’ own prosocial contributions in unrelated causes (H3). For these studies we collaborated with two local nonprofit organizations to conduct donation drives for books and used clothing, respectively, lasting around three weeks and consisting of two parts: reading about a disaster and donating to the drive. Participants first come to the lab and read a PowerPoint presentation on a recent natural disaster as in previous studies.

Participants also read about the disaster relief efforts conducted by robots (versus humans, Study 5; or different types of robot-human relationships tested above, Study 6). After completing several filler questions, participants saw on the exit page an advertisement on the donation drive. A donation site was set up to collect donations. As predicted, reading about robots (vs. humans) or robots that lacked autonomy (vs. high in autonomy as in taking a partner role with humans) led to significantly lower contributions in the book and clothing donation drives. These findings suggest that featuring how machines/robots assist in prosocial missions should be carefully managed to sustain high inspiration and ensure consumers’ own contributions.

SESSION OVERVIEW
In this session, we examine markets as socially constructed platforms that facilitate value exchange (Vargo and Lusch 2004), provide scaffolding for resources (material and symbolic) to flow within and among complex and ever-evolving social arrangements (Thornton 2004) and tame complexity. We examine material vessels of value as resources and how these resources flow within social systems to enable everyday life. We draw attention to the complex manner in which materiality impacts markets and conversely how markets shape material relations. The session is composed of four empirical studies highlighting the interdependence of materiality and markets: two address the question “How does materiality shapes markets?” and two address the question “How do markets impact material arrangements?”

The first presentation demonstrates how neoliberalist ideas of personal financial responsibility shape and reshape the market for consumer goods. The authors uncover the manner in which the acquisition of materiality through the neoliberalist lens requires consumers to draw and negotiate stark divisions between material wants. They unpack complex neoliberal-driven consumer sense making that transforms the landscape of consumer goods into justifiable needs and unjustifiable wants, into good and evil material acquisitions. They reveal the manner in which consumers, shamed by the neoliberalist gaze, avoid or apologetically consume as rewards materiality with luxury attributes. The second presentation shows how materiality shapes the global distribution of a social practice. They demonstrate how a regional practice, surfing, is distributed globally through a stylized and codified retailscapes governed by structures of common difference (Wilk 1995) that enables elements of the local to be retained. They demonstrate that the retailscapes’ material configurations scaffold the exchange of value (material and symbolic) and organize the market. The third presentation reveals how shifting infrastructures, social norms and markets frame and reframe consumers’ material relationships and practice assemblages. They show how confluentes of market forces, including new modes of bike access, shape uses and meanings of bicycle helmets across a range of practice contexts. The last presentation demonstrates empirical evidence of how the exchange of intimately singular materiality (bodily organs) is shaped by a highly regulated market for organ donation. This research uncovers themes of navigating participation, negotiating the process and dynamic sourcing of actor resources to precipitate this intimate exchange. Organ donors employ a variety of personal, emotional, physical, social, political and market-facing sources to accrue resources which serve as precursors to activation of additional resources necessary for value creation.

We structure the session as a series of four empirical presentations tightly tied to the theme of materiality and markets. Each presentation will be 12 minutes leaving 20-25 minutes for discussion and debate. While all the presentations have implications for material arrangements, social practices and market configurations, they borrow from a range of intertwined theories including social practices, assemblage, value co-creation and structures of common difference. This session will facilitate scholarly discussion of the complex interplay between markets and materiality. We expect lively audience participation and involvement based around differing substantive and contextual interests as well as eclectic theoretical perspectives.

Neoliberalism: the Paradox of Agency and Responsibility in the Acquisition of Materiality

EXTENDED ABSTRACT
Neoliberalism is the doctrine that “market exchange is an ethic in itself, capable of acting as a guide for all human action” (Harvey 2007: 3). Central to neoliberalism is the primacy of private, individual agency to act within markets and for markets to guide human behavior toward positive, prosocial action. With agency comes requisite responsibility. Individuals within the market are agentic and ultimately responsible for their behaviors. Here, we apply the neoliberal lens to examine how it shapes the market through moralizing the acquisition of materiality.

Consumers within the neoliberal framework are agentic actors tempered by the ethics of the market, specifically the concepts of contractual fidelity and the notions of fair trade and value in kind (Marron 2013). Consumers are charged with conducting themselves within the rules and norms of the market and in engaging in decision-making that supports ethical exchange. Here, we examine consumers who have accumulated debt beyond their ability to abide by their contractual obligations. They are in a crisis state and are danger of default. Our participants have given themselves over to a debt management program (DMP) designed to help consumers pay off past debts and to educate them on financial responsibility to avoid future debt crises. The primary methodology DMPs utilize is budgeting. DMPs work with indebted consumers to make good on current financial obligations and to create budgets to guide present and future market interactions. An extensive literature in marketing has explored how consumers attempt to control their own behavior and resist the urge to buy (Hoch and Loewenstein 1991; Rook 1987). Effective strategies require clear standards of behaviors, tools for monitoring behaviors against standards, and managing goal conflict (Baumeister 2002). Budgets are a common strategy consumers use to allocate resources towards their goals. Budgets prioritize needs (e.g., shelter, food) with any leftover funds available for wants. This
research stream assumes a rational consumer and uses experimental contexts to understand deviation from normative behavior.

Wants and needs are foundational concepts and categories in economics and marketing; however, prior scholarship does very little to conceptualize the difference between wants and needs. While economists generally define needs as anything urgent and necessary for survival (Galbraith 1998), consumer behavior scholars are more likely to conceptualize needs as those goods society would deem to be “decencies” or “social necessitates,” which are items needed to preserve a certain level of respectability (Berry 1994; Ger and Belk 1999; Buttle 1989). Wants are typically conceptualized as being less legitimate than needs, with economists arguing that wants are artificially created by advertising. Goods are often categorized as hedonic (wants) or utilitarian (needs) when considering consumer choice (Hirschman and Holbrook 1982). Further, given the ever-increasing selection of goods, the broadening of status and lifestyle games in modern economies (Holt 2004; Thompson and Haytko 1997), and the ability of marketers to make luxuries seem to be necessities (Hamilton, Denniss, and Baker 2005), it is not surprising that consumers themselves often struggle to categorize wants and needs. The socially prescribed bundle of necessary consumer goods has increased over time in parallel with expanding credit card usage (Bernthal, Crockett and Rose 2005; Braun, Zolfagharian and Belk 2016; Peñaloza and Barnhart 2011), further blurring the distinction between wants and needs.

Even a cursory review of treatments of want and need, whether scholarly or secular, reveals that the two are suffused in rhetorical discourses: the way wants and needs are presented often suggests that needs are justifiable and acceptable, but wants have a contested moral status. As Braun et al. (2016, 211) note, wants are considered “indulgences and inferior to needs.” Campbell (1998) provides an overview of what he calls the rhetorics of need and want. The rhetoric of need in American culture hails from the Puritan tradition that approves of consumption of items that satisfy utilitarian needs but condemns wanting. While Maslow’s famous hierarchy of needs reflects this rhetoric to some degree as utilitarian needs appear at the base of the pyramid, his work acknowledges psychological and social needs, such as the need for connection to others, respect, and self-actualization (Maslow 1970).

We argue that adherence to neoliberalism structures consumer agency forcing them to make tradeoffs between needs and wants to perform responsibly in the market. We examine how consumers create their own categories to justify their spending in real life. While lab studies only allow for short-term impulses, our data are longitudinal. Specifically, our data consist of surveys and interviews with consumers, and interviews with DMP counsellors throughout the program journey. This allows us to witness longitudinally the perceptions, meanings and behaviors of indebted consumers and their counsellors. It explains the data where the indebted clients own responsibility. Most do not blame their debt status on the marketplace deception, but assert that they face a situation of their own making. The issue of “responsibility” has become a defining feature of the current thinking of neoliberalism. We focus on want and need as rhetorics that legitimate or de-legitimate purchase. Vulnerable consumers in a DMP are particularly prone to find rhetorics that convert wants into needs. Emotional needs, situational needs, and social obligations enable consumers to justify purchase of wanted items. It is clear that the traditional dependence on the financial literacy model is not appropriate. The understanding of wants and needs from an academic perspective does not match the lived experience of our indebted consumers. Our results inform the understanding of consumer want, and also offer insights for improving the financial success of consumers.

**Retailscapes as Structures of Common Difference: How Materiality Shapes Global Markets and Local Communities**

**EXTENDED ABSTRACT**

Global markets are constructed through the movement of people, images, technology, money and ideas (Appadurai 1990). The fluidity of global phenomena requires stabilizing mechanisms to establish enduring connections across diverse locales. Structures of common difference (SCD) have been recognized as a common global form that enables the movement of global symbols throughout local spaces (Wilk 1995). These common structures have been explored in the context of beauty pageants (Wilk 1995), global brands (Thompson and Arsel 2004), and subcultures of consumption (Kjeldgaard and Askegaard 2006). We extend the study of common global structures by exploring retailscapes as SCD.

Retailscapes organize materiality to create value-laden markets and provide an avenue for the global movement of multiple phenomena. Retailscapes bring together Appadurai’s (1990) five global scapes – ethnoscapes, mediascapes, technoscapes, financescapes and ideoscapes – into one comprehensive platform for globalization. They provide spaces and places for firms to interact and engage in exchange with customers (Arnould, Price and Tierney 1998). Meshing global structures within local communities poses a challenge for companies wanting to engage with a variety of cultures in a cost-effective way. To design retailscapes that appeal to different cultures, maintain brand continuity, and support a specific global market, an understanding of globalization and the processes through which the global coexists with the local is needed. This research uncovers the role of retailscapes in connecting global markets with local communities.

Traditional approaches to globalization promote the idea of global hegemony, while more recent views suggest that the global is adapted to the local and becomes glocal (Robertson 1995). Inspired by prior studies on surfing (e.g., Akaka and Schau 2019; Canniford and Shankar 2012) and annual global sales of US$15.15 billion, we examine the glocal nature of surf retailing, specifically design and organization of materiality within surf shops. Observation of surf retailers reveals a distinct pattern to the store layout, product assortment and aesthetic that supports a particular market mythology, e.g., a narrative centered on the practice of surfing, rather than a brand-oriented narrative. Our research uncovers that while non-surfers comprise the bulk of revenues in this market, the local community is composed of surfers who rely on the same retailers for a variety of resources that enable them to live a particular lifestyle, develop self-identity and engage in the practice of surfing. We address the following research questions: how do surf retailers (local and global) construct, reify and communicate the surfing narrative through their retailscapes? Is there a global retailscape pattern related to the narrative? How do global common structures foster or support the formation of local communities?

To explore the glocal nature of surfing, we conceptualize retailscapes as “structure[s] of common difference” (SCD), that connect dominant global forms with local communities (Wilk 1995). Wilk (1995: 111) draws on Appadurai’s work to explore how a “global cultural system promotes difference instead of suppressing it, but difference of a particular kind. Its hegemony is not of content, but of form” (p. 118). The intersection between global and local is both heterogeneous and homogeneous; it is the commonality of cultural
form that enables us to identify differences in cultural content. While globalization is presumed to be hegemonic imperialistic intrusion of Western artifacts, ideas and practices (e.g., Levitt 1993), this assertion mutes the agency of localities and obscures the role of common forms that enable local cultural differences to be recognized.

By examining surf retailers for global common structures and local meanings, we see how local and global surf brands originating from different regions and nations create, reify and perpetuate myths of 1960s California and the idealized/updated figure of the surfer, through their retailscapes. Products and images are designed primarily to attract nonsurfers to buy surf-related products, like apparel, and utilize the common myth to shape the global surfing market, rather than promoting a single brand or product. Using the idealized California of the 1960s as an inspiration, the surf lifestyle is widely accepted and used in surf retailscape around the world. This narrative provides a common understanding of what surfing is and a means for people to engage with a global practice and market. Likewise, local communities utilize global symbols to distinguish themselves from other locals engaging in surfing and the market.

The global retailscape establishes an enduring structure that perpetuates as it moves across space and time. Even as stark differences in surfing culture can be seen across different local communities – what they wear, how they talk, the formality of relationships – the surfshop retailscape translates across communities in a relatively consistent manner. The types of products, store layout and global brands remain the same. Furthermore, the evolution of surfing over time reveals changes in the equipment (e.g., longboard to shortboard) and the performance (e.g., surfing on the wave vs. above the wave). Throughout these changes, the common structure of the retailscape remains the same. Specific products, brands and styles are replaced, but the dominant narrative of surfing and in-store experience is largely unchanged. These retailscapes stabilize the relationship between the global market and local communities and help to sustain the global nature of surfing culture. Our research highlights the importance of materiality of retailscapes in maintaining and growing subcultures of consumption, particularly those that span across both local and global contexts.

Bicycle Helmets and Biking Practices: How Shifting Market Contexts and Adjacent Practices Shape Practice Element Misalignment

EXTENDED ABSTRACT

Practice theory emphasizes whether and how objects are mobilized and integrated with each other into one or more practices (Hand and Shove 2007; Schatzki 2010). Consumer-object relationships are an essential element of many social practices and practices are “intrinsically connected to” objects (Rechwitz 2002; Schatzki 2002, 106). Recent research highlights how object-worlds “are constantly in flux” and calls for more attention to temporal rhythms in everyday life that account for the materiality of practices (Rinkinen, Jalas, and Shove 2015). One issue is that of material misalignment, which occurs when a practice element “demands attention, because it is experienced as hindering, threatening, or harming proper performance.” (Woermann and Rokka 2015, 1499). While most material misalignment research focuses on temporary misalignment across an array of practices, either caused by an event or the natural entropy of practice elements that drives temporary misalignment (Woermann and Rokka, 2015; Dion, Sabri, and Guillard 2014; Phipps and Ozanne, 2017), our research considers elements that are chronically misaligned with their practices, with a focus on bicycle helmets.

We examine how a helmet’s alignment with the practice of bicycling changes as it moves across time and space and is bundled with and interrupted by different practices and market structures. We contribute to the literature on element misalignment within a practice and between practices. First, we examine element misalignment in the context of the lifecycle of a practice extending from childhood to young adult. Second, we examine how the practice itself is embedded in the practice world and alignment is affected by how elements bump up against adjacent practices. We show how bringing an element back into alignment with a practice depends not only on how the element is embodied within that practice, but also on the way that practice element fits with other adjacent practices. Specifically, we demonstrate that embodiment fluctuates widely, and isn’t just a function of the temporary entropy of practice elements, but a function of the way in which the practice itself is embedded in a number of other practices, which results in shifting embodiment as the other elements of the practice array shift, and further contribute to material misalignment.

Bicycling is an increasingly popular activity in the United States with 34% of Americans reporting they rode a bicycle in the past year (Breakaway Research Group 2015). Head injuries are the most common cause of bicycle-related death and serious injury (Centers for Disease Control and Prevention 1999). Bicycle helmets are the single most effective way to prevent head injury in a bicycle crash but usage statistics show that a majority of U.S. adult bicyclists do not wear a helmet while riding (Breakaway Research Group 2015). Bicycle sharing programs are increasingly popular in the United States, such that the number of bicycle sharing bikes more than doubled in 2017 alone (National Association of City Transportation Officials 2017). Our research was conducted through a series of 175 structured and 28 in-depth interviews, as well as a survey of 528 bicyclists in and around Eugene, Oregon, a city that ranked second in the nation for bicycle commuting, with 8.5% of its population reporting using bicycles as their primary method of transportation (Eugene Public Works 2008). Interviews occurred shortly after the installation of a new bicycle-sharing program in Eugene with the explicit mission of improving consumer and community wellbeing. This enabled investigation of the way this infrastructure change affected existing bicycling practices and material misalignment within practices at a community and individual level. Research is ongoing with particular emphasis on the unfolding material and practice consequences of the bike sharing program.

We uncover a complex intersection of temporality, spatiality, and practice surrounding the bicycle helmet. The helmet’s meaning and alignment shifts dramatically based on its current temporality, spatiality, and practice bundles. We begin by examining the alignment of the helmet over childhood to early adulthood, uncovering that the initial material alignment of the helmet is not recaptured when the practice itself is reformed. The helmet object is aligned with other practices, but despite a desire to bring this element back into alignment, we uncover only selective alignment in the context of select spatialities. Embodied and embedded complexities together contribute to this persistent material misalignment of the helmet. Embodied complexity consists of both physical and identity misalignment, as we uncover a paradoxical association that helmets simultaneously signify expertise and inexperience on the part of the bicyclist, both of which are identity incongruent for the average bicyclist. Additionally, we uncover misalignment as a result of adjacent practices, such that one element in a practice bundle is differentially affected by adjacent practices so as to throw it out of alignment with the core practice. Despite the properties of this element being
central to the practice itself, this differential misalignment can precipitate the exclusion of this element from the practice itself.

Further exacerbating this misalignment is the introduction of a new market structure in the form of a bicycle sharing program to the community. On one hand, the bicycle sharing program aligns beautifully with both community goals and everyday bicycling practices. However, the bicycle sharing program also exacerbates helmet misalignment in the community. Helmets are not provided when utilizing the sharing program, and participants whose bicycling practices began or shifted to center around use of the sharing program did not include helmets in their practice. This interruption of existing bicycling practices extended even to participants who previously had consistently worn a helmet when riding their own bicycle.

**Supply Money Can’t Buy: Transcendent Consumer Experiences through Living Organ Donation**

**EXTENDED ABSTRACT**

Marketers strive to generate demand for their offerings. Yet for some marketers, demand may outpace supply. This is most evident in organ and tissue transplantation, where revenue is constrained by supply (Cho et al. 2015). Consider a recent University of Pittsburgh Medical Center television commercial that depicts a line of individuals slowly making their way through an ominous tunnel, with the voice over: “At UPMC, living donor transplants put you first so you won’t die waiting.” Where most marketing research in healthcare considers a dyadic relationship between clinicians and their patients, UPMC’s message foregrounds transplant offerings as a triadic relationship between a firm, patient, and donor. Marketing and consumer research in healthcare domains theorizes roles for consumer participation and compliance for the possibility of attaining desired (Bradford, Grier, and Henderson 2017; Dellarde, Gilly, and Graham 2004; Hausman 2004) or transformative (Wong and King 2008) outcomes. Transformative outcomes are more often associated with extraordinary experiences that may result in transcendent consumer experiences. Yet, it is likely that such transcendence is possible through healthcare offerings. Thus, this research explores how healthcare may result in transcendent consumer experiences, and influence markets.

Schouten and his colleagues (2007) characterize transcendent consumer experiences (TCEs) as those consumption experiences that occur through the marketplace which engender feelings of awakening, foster a connection with something larger than the self, encourage the exploration of personal boundaries, and influence consumers’ attachment to supporting brands and marketing activities. TCEs often result when consumers engage in extraordinary events such as skydiving, river rafting, mountaineering or Burning Man (Celsi, Rose, and Leigh 1993; Kozinets 2002; Price, Arnould, and Tierney 1995; Tumbat and Belk 2011), as well as through brands and brand communities, as with Harley-Davidson or Xena: Warrior Princess (M-Alexander, Schouten, and Koenig 2002; Schau, Muñiz, and Arnould 2009). Where prior research finds such transcendent consumer experiences may result in brand loyalty, this research explores how TCEs resulting from healthcare may influence individuals’ attachment to such offerings, and inspire consumers to promote such experiences.

Healthcare is shaped by institutional logics—beliefs and rules that influence consumers’ and organizations’ behavior (Beverland, Wilner, and Micheli 2015; Dunn and Jones 2010; Lawrence and Suddaby 2006). Some logics found to influence healthcare include care and science, professional and business, or care and research (Dunn and Jones 2010; Reay and Hinnings 2009; Toubiana and Zietsma 2017). For example, the care and science logics emerge from the institutions that train clinicians and those that provide the environment for clinical care (Dunn and Jones 2010). Ertimur and Coskuner-Balli (2015, p.40) describe the healthcare market as one where “the care and science logics have coexisted...these logics provide multiple and, from time to time, conflicting prescriptions to stakeholders in the market.” The coexistence of logics may influence a market by shaping its course as tensions between logics meld with or contest one another (Dunn and Jones 2010; Kozinets and Handelman 2004; Pache and Santos 2013; Toubiana and Zietsma 2017; Weijo, Martin, and Arnould 2018). In particular, marketing research explains how institutional logics may emerge such that existing logics are challenged, replaced, or evolve by new logics introduced by institutional entrepreneurs (Dunn and Jones 2010; Ertimur and Coskuner-Balli 2015; Giesler 2006; Humphreys 2010; Scarabotto and Fischer 2014). The present research contributes an explanation of how healthcare transcendent consumer experiences may result from the melding of healthcare logics with an additional one: benevolence.

Research finds individuals value marketing activities that are central to transcendent consumer experiences (Schouten et al. 2007). To understand the relationship between TCEs and healthcare institutional logics, this ethnographic study explores a consumer-led marketing activity: the 2018 Guinness Book of World Record attempt for the largest gathering of living organ donors. This research is guided by the following questions: How do TCEs manifest in healthcare? What is the relationship between institutional logics and TCEs? And, how do those logics influence one another? Prior research finds that coexisting logics may evolve or disrupt markets through the incorporation of new logics (Giesler 2006; Humphreys 2010; Scarabotto and Fischer 2014; Toubiana and Zietsma 2017). This research contributes an understanding of an additional institutional logic operating within the realm of healthcare, benevolence, which may result in transcendent consumer experiences. More specifically, this research contributes an explanation of how co-existing logics may lead to amplification of healthcare logics; how a benevolence logic may result in a transcendent consumer experience; and, how institutional entrepreneurship may result from TCE to support supply creation within healthcare markets.

Paper #4: Fighting Misinformation on Social Media Using Crowdsourced Judgments of News Source Quality
 Gordon Pennycook, University of Regina, USA
 David Rand, Massachusetts Institute of Technology, USA

SESSION OVERVIEW

Becoming wise means becoming more discerning, but social media has made it difficult for people to discern legitimate news from misinformation. Although misleading news is hardly a new phenomenon, the advancement of social media has accelerated the pace at which falsehoods can spread. Some estimates suggest fake news can travel as much as six times faster than legitimate news (Vosoughi, Roy, & Aral, 2018).

To complicate things further, political polarization is driving an unprecedented demand for partisan news—real or fake. Marketing researchers are in a unique position to answer two fundamental questions: What are the psychological consequences of fake news in a polarized environment? What can be done to address the seemingly unending problem of fake news proliferation on social media? The objective of this session is to address the psychological mechanisms and consequences of fake and polarizing news, and to address reasonable steps social media consumers can take to combat the spread of fake news.

In our first paper, Gonzalez, Jung, and Critcher address the polarizing effect of opposite-partisan perspective-taking on perceptions of truth in online news media. Opposite-partisan perspective-taking drives consumers to perceive greater truth in headlines consistent with their own partisan leaning. This occurs regardless of whether or not a headline is fake or real. The evidence suggests that trying to understand an opposing political perspective can backfire, causing consumers to view more bias in opposite-partisan others.

Our second paper, by Catapano, Tormala, and Rucker, explores how perspective-taking can lead to greater polarization of one’s attitudes. They find that taking an opposite-partisan perspective leads people to become less receptive to others’ arguments and less open to changing their own attitudes. The researchers propose that this is because participants taking the perspective of someone with an opposing viewpoint are likely reminded of how different their own perspective is from those on the opposing side of a debate.

Han, Euh, Wang, and Rao examine the possibility that leveraging a care/harm moral foundation might lead consumers to be less likely to disseminate fake news on social media. By framing an appeal to be congruent with different targets of a care/harm moral foundation among liberals and conservatives (universal caring for liberals, and parochial caring for conservatives), participants are less likely to share political falsehoods on social media.

Finally, Pennycook and Rand investigate the use of crowdsourcing as a tool to fight the spread of misinformation. Despite a political environment where polarization is the norm, the authors find that people still overwhelming trust mainstream news sources more than extremely partisan sources. They find that laypeople can be as accurate as professional fact-checkers at assessing the veracity of news, and suggest using algorithms to up-rank news with high crowdsourced trust ratings.

Together, these papers address the psychological mechanisms and consequences of fake news and political polarization, and provide novel theoretical and practical insights for improving online media consumption. This session takes steps to propose interventions that make consumers less susceptible and more empowered to fight fake news.

Opposite Partisan Perspective-Taking Leads to Polarized Assessments of Political News Truth

EXTENDED ABSTRACT

The rise of online media in a partisan era has driven even reasonable consumers into echo chambers. Many propose that a remedy to polarization is for one to get perspective, to learn from someone at the opposite end of the political spectrum. However, attempting to do so in a polarized environment can backfire. We propose that opposite-partisan perspective-taking will lead people to evaluate partisan-congruent news articles as more truthful, regardless of whether or not the article is legitimate or fake news.

Research on fake news has focused on its proliferation and how this proliferation impacts society. Exposure to misinformation can lead people to confuse fact with fiction, causing doubts about the accuracy of legitimate information (Rapp & Salovisch, 2018). Fake news has also been found to spread at a rate six times faster than legitimate news (Vosoughi, Roy, & Aral, 2018). Making matters worse, social media exposure to opposite-partisan messages leads to polarized partisanship (Bail, Argyle, Brown, Bumpus, Chen, Hunzaker, Lee, Merhout, & Volfovsy, 2018), but does polarization change perceptions of political truth?

By one account, attempting to gain a different perspective could dampen one’s polarized attitudes. Perspective-taking research demonstrates that it can reduce attitude entrenchment (Tuller, Bryan, Heyman, & Christenfeld, 2015), but evidence also suggests people are likely to perceive greater bias in a person with whom they disagree (Kennedy & Pronin, 2008). We propose that when a person takes the perspective of an opposite-partisan other, they will perceive greater bias in opposite-partisan worldviews, leading them to judge partisan-congruent articles as more truthful.

For our first study we predicted that participants would become polarized when taking the perspective of an opposite-partisan other,
leading them to think partisan-congruent news headlines would be more truthful. We recruited 396 participants from Amazon’s Mechanical Turk (MTurk) and randomly assigned them to one of three perspective conditions: liberal, conservative, and control. We first measured participant political orientation, and afterwards participants were told the purpose of the study was to examine how people distinguish between real and fake news. They were told they would see a series of headlines that might appear on a Facebook newsfeed.

Participants in the control condition were asked to rate the extent to which they were interested in reading each story. To induce perspective-taking, participants in the experimental conditions first assessed how truthful a future participant who is either left-leaning in the liberal condition, or a right-leaning person for the conservative condition, would rate each of the headlines (1 = Definitely fake, 7 = Definitely real). Before starting, participants were told not to search any of the headlines online, and were excluded from analyses if they indicated on a later attention check that they had. Their task consisted of assessing the likelihood that this future participant would rate a headline as more fake or real. We used headlines from Pennycook, Cannon, and Rand (2019), which consisted of 12 fake and 12 real headlines, evenly split between liberal- and conservative-leaning headlines. After completing the first set of ratings, participants in all conditions were told they would see the same collection of headlines, but this time they would rate the percentage likelihood they thought the story was fake versus real news (0% = Definitely fake, 100% = Definitely real).

We tested whether taking an opposite-partisan perspective led to more polarized assessments of article truth—even when controlling for the actual truth of the headline. We conducted a mixed model in which we included fixed effects of perspective, article orientation, participant orientation, and article truth. To account for the non-independence of participants’ multiple judgments, we included a random effect of participant and headline. We found a significant three-way interaction between perspective, article orientation, and participant orientation, $F(2, 9080) = 13.83, p < .001$, suggesting that participants became more polarized in their own views when taking an opposite-partisan perspective. Decomposing this interaction further, we found that liberal participants in the conservative perspective condition found liberal-leaning articles to be significantly more truthful ($t(9080) = 4.18, p < .01$), and conservative participants in the liberal perspective condition found conservative-leaning articles to be significantly more truthful ($t(9080) = 3.32, p < .01$).

Study 2 ($N = 1,276$) was a pre-registered replication of Study 1 using new headlines. Once again, we found that our perspective manipulation led to polarized assessments of article truth. We found a significant three-way interaction between perspective, article orientation, and participant orientation ($F(2, 29310) = 18.91, p < .001$). Decomposing this interaction further, we again found that liberal participants in the conservative perspective condition found liberal-leaning articles to be significantly more truthful ($t(29310) = 3.57, p < .01$), and conservative participants in the liberal condition found conservative-leaning articles to be significantly more truthful ($t(29310) = 4.57, p < .01$).

Study 3 ($N = 1,436$) was a pre-registered replication and extension of Study 2. Using the same headlines from Study 2, we removed news sources to examine if our effects would hold without the partisan signaling of these sources. As predicted, we found a significant three-way interaction between perspective, article orientation, and participant orientation ($F(2, 32990) = 31.06, p < .001$), where liberal participants in the conservative perspective condition found liberal-leaning articles to be significantly more truthful ($t(32990) = 3.91, p < .01$), and conservative participants in the liberal perspective condition found conservative-leaning articles to be significantly more truthful ($t(32990) = 5.05, p < .01$). To better understand the mechanism accounting for our perspective manipulation effect, we included in the model a new measure of political differences assessing the degree to which participants perceived greater political bias in opposite-partisan worldviews. Including our political difference measure attenuated the three-way interaction, but not completely, $F(2, 32990) = 18.24, p < .001$, lending evidence that greater perceived bias in opposite-partisan worldviews led participants to give polarized assessments of article truth.

This research is particularly relevant to political marketers, where promoting opposite-partisan articles, however well-intentioned, could backfire and have the opposite effect of facilitating understanding. In light of this, marketers should consider alternative methods of advertising to online political news consumers.

**Perspective-Taking and Self-Persuasion: Why “Putting Yourself in Their Shoes” Reduces Openness to Attitude Change**

**EXTENDED ABSTRACT**

People are more divided, and less open to opposing views, than they have been in years. Nowhere has this been more apparent than in the drifting apart of our two major political parties, leading to unprecedented levels of polarization (Pew Research Center, 2017). This problem is exacerbated by selective exposure—individuals predominantly attend to information that supports their existing attitudes, beliefs, and values (Eagly, Kulesa, Chen, & Chaiken, 2001; Hart et al., 2009; Iyengar & Hahn, 2009; Smith, Fabrigar, & Norris, 2008), and trust news sources and individuals who reinforce their existing attitudes.

Previous research suggests that perspective-taking should be a powerful tool for bridging these growing gaps (e.g., Galinsky, Ky, & Wang, 2005). The current research asks whether perspective-taking actually helps reduce attitude polarization, specifically in the context of self-persuasion. Previous work on self-persuasion suggests that when people generate counterattitudinal arguments, they often shift their attitudes toward those arguments (e.g., Brihötl, McCasin, & Petty, 2012), without any outside input. Based on extant research, we might expect this effect to be amplified by perspective-taking. However, we suggest that when people take the perspective of those with different values, they end up generating ideas that are consistent with the other side’s values and morals rather than their own. As a result, they are actually less receptive to the other side’s position, and show reduced attitude change, compared to if they had simply reflected on arguments for the other side without trying to see the other side’s perspective. We test this hypothesis in two preregistered studies.

In Study 1 ($N = 484$), participants recruited from Reddit (focusing recruitment on political subreddits) began by reporting their attitudes toward Universal Basic Income (UBI) on a 100-point scale (Against to In favor). Then, participants were told that at a later date, they would interact with another redditor, and received background information about this user, including that they were of the opposite attitude and political ideology. Then, they were asked to generate one argument for the counterattitudinal viewpoint, with varying instructions across two conditions. In the perspective-taking condition, participants were asked to take the perspective of the person who they would interact with and generate one argument that that person would give in support of their own view (adapted from the perspective-taking literature, e.g., Clore & Jeffery, 1972). In the control condition, participants generated one argument for the opposing viewpoint, with no additional instructions to take anyone’s perspective.
tive. After generating the argument, participants were again asked to indicate their own attitude on the 100-point scale, and they also reported their receptiveness toward the view they wrote about, and how congruent their argument was with their own values.

We found a significant effect of the perspective-taking manipulation on value-congruence, receptiveness to the opposing view, and attitude change, $p < .05$. In addition, perceived value-congruence mediated the effect of perspective-taking on both receptiveness (95% CI [-.19, -.02]); $p = .02$ and attitude change (95% CI [-.09, -.00]; $p = .02$). Thus, individuals who tried to take the perspective of the opposition generated arguments that were less congruent with their own values, which undermined their receptiveness to the opposing view and reduced attitude change. This result replicated with a larger sample recruited from an online panel company ($N = 998$).

In Study 2 ($N = 1248$), we aimed to provide further evidence for this process using a moderation approach. If the negative effect of perspective-taking on receptiveness and attitude change is driven by the perception that the arguments generated are incongruent with one’s personal values, the effect might be attenuated when people take the perspective of someone who disagrees on the target issue yet has similar overall values. To investigate this possibility, we included two perspective-taking conditions, varying whether participants took the perspective of someone with a similar or different political ideology.

As in Study 1, participants began by reading a description of the target issue (UBI) and indicating their initial attitudes. Then, participants were randomly assigned to one of three argument generation conditions. In the perspective-taking/different ideology condition, participants generated an argument that a person with the opposite political ideology would give for the opposing view on UBI. In the perspective-taking/same ideology condition, participants generated an argument that a person with the same political ideology as themselves would give for the opposing view on UBI. In the control condition, participants simply generated a counterattitudinal argument. Then, participants reported their attitudes, receptiveness, and perceived value-congruence as in Study 1.

We found a significant overall effect of perspective-taking on value-congruence, receptiveness, and attitude change, $p < .001$. Participants showed less receptiveness and attitude change in the perspective-taking/different ideology condition than in the perspective-taking/same ideology and control conditions, $p < .001$. In addition, participants showed marginally more receptiveness, $p = .06$, and significantly greater attitude change, $p < .001$, in the perspective-taking/same ideology condition rather than the control. Mediation analyses confirmed that perceived value-congruence mediated the backfire effect of perspective-taking on both receptiveness (95% CI [-.04, -.08]) and attitude change (95% CI [-.01, -.04]). Thus, taking the perspective of someone with a different (similar) overall political ideology accentuated (mitigated) the backfire effect of perspective-taking observed in Study 1, by facilitating the generation of value-incongruent (value-congruent) arguments.

These studies suggest that perspective-taking might not be a cure for polarization, as it has been championed, but rather that it can facilitate polarization and thus become yet another factor contributing to the growing chasm between people with opposing viewpoints. This finding suggests that marketers and other influencers should resist the temptation to harness perspective-taking as a means of opening people up to different views. When we ask individuals to put themselves in the other side’s shoes, or write a review about why someone else would like a particular product, we may inadvertently remind them of how different their own values are from those of others, foster ideas that are incongruent with those values and, ultimately, reduce their openness to attitude change. Remedies and implications for consumer behavior will be discussed.

**Leveraging Care/Harm Moral Foundation Among Liberals and Conservatives to Reduce the Dissemination of Fake News**

**EXTENDED ABSTRACT**

A number of studies have been conducted to develop a solution to the problem of the sharing of false stories online. Further, practitioners have attempted to address the issue directly, employing lay theories of information processing. For instance, in December 2017, Facebook began adding “Disputed” tags to stories that had been debunked by third party fact-checkers. However, Pennycook et al. (2018) found that this tag was not very effective and could even backfire among Trump supporters. Clayton et al. (2019) tested three types of warning messages—a general warning which shows tips for spotting false news, tagging news as “disputed”, and tagging news as “Rated false”. They found that “Rated false” tag lowers people’s perceived accuracy most, but none of these messages was effective in changing the willingness to share false news. All the existing approaches employed in practice appear to be ineffective, and the task of determining the accuracy of false news stories is daunting. Therefore, rather than relying on news providers to police the veracity of information, we focus on the news consumer and assess whether we can stimulate vigilance by strengthening individuals’ internal motivation to identify fake news and to share information responsibly.

In the current study, we develop a new way to reduce people’s intention to share false information based on the growing body of research on political ideology and its dispositional nature. Psychological research demonstrates that liberals and conservatives differ from one another in terms of motivational interests and moral foundation. The empirical observation that fake news shared over social media substantially favored Donald Trump over Hillary Clinton (Bucciol, 2018) and conservatives retweeted pro-Republican fake news more often than liberals did pro-Democrat ones (Badawy et al., 2018) could be explained based on this ideological asymmetry (Jost et al., 2018). We suspect that the most effective message to change the willingness to share questionable information will be different for conservatives and liberals, based on differences in their ideology.

We focus on care/harm foundation, an element of moral foundations, because, when this moral foundation is active, individuals tend to reduce their reliance on heuristic thinking and use systemic judgment strategies for people they care about (Lerner and Tetlock, 1999). Both liberals and conservatives subscribe to care/harm foundation, but the target of their caring differs (Haidt, 2012). Liberals are more likely to value universalism and steer away from in-groupism such as nationalism. Conservatives, in contrast, are more parochial—concerned about their groups, rather than all of humanity. This parochial caring also corresponds to conservatives’ strong relational motivation, such that they place great emphasis on group conformity, loyalty, and group cohesion, and distinguish friends from foes swiftly. Thus, we predict that persuasive appeals that are congruent with different targets of care/harm moral foundation of conservatives and liberals might reduce their willingness to share fake news.

To test our core premise, we presented participants with fourteen news headlines that were entirely untrue (seven stories were selected to be Democrat-consistent and Republican-consistent respectively, drawn from Pennycook and Rand, 2018) and measured their willingness to share each headline (e.g., How much would you be willing to share this story online? How much would you be will-
The reliability of news websites, and then adjusting social media platforms for the spreading of misinformation (Lazer, 2017). By this account, people believe fake news because it is consistent with their political ideology. As a result, sources that produce the most partisan content (which is likely to be the least reliable) may be judged as the most trustworthy. Third, other research suggests that liberals and conservatives differ on various traits that might selectively undermine the formation of accurate beliefs about the trustworthiness of news sources (Jost, 2017). Finally, it also seems unlikely that most laypeople keep careful track of the content produced by a wide range of media outlets. In fact, most social media users are unlikely to have even heard of many of the relevant news websites, particularly the more obscure sources that traffic in fake or hyper-partisan content.

Here, we investigate whether the crowdsourcing approach is effective at distinguishing between low- versus high-quality news outlets. In the first study, we surveyed N=1010 Americans recruited from Amazon Mechanical Turk (MTurk); in the second study, we surveyed N=970 Americans recruited from Lucid, a subject pool that is nationally representative on age, gender, ethnicity, and geography. In the second study, we also recruited eight professional fact-checkers to compare to the laypeople. In each study, participants were shown a set of 60 new sources URLs asked if they were familiar with each domain, and how much they trusted each domain. We included mainstream media outlet websites (e.g., cnn.com, npr.org, foxnews.com), websites that mostly produce hyper-partisan coverage of actual facts (e.g., breitbart.com, dailykos.com), and websites that mostly produce blatantly false content (which we will call “fake news”, e.g., thelastlineofdefense.org, now8news.com).

The results show that there are clear partisan differences in trust of mainstream news: in both studies, Democrats trusted mainstream media outlets significantly more than Republicans (S1: 11.5 percentage point difference, F(1,1009) = 86.86, p < .0001; S2: 14.7 percentage point difference, F(1,1970) = 104.43, p < .0001). The only exception was Fox News, which Republicans trusted more than Democrats (post hoc comparison; S1: 29.8 percentage point difference, F(1,1004) = 243.73, p < .0001; S2: 20.9 percentage points, F(1,965) = 99.75, p < .0001).

Hyper-partisan and fake news websites, conversely, did not show consistent partisan differences. In Study 1, Republicans trusted both types of unreliable media significantly more than Democrats (hyper-partisan sites: 4.0 percentage point difference, F(1,1009) = 14.03, p = .0002; fake news sites: 3.1 percentage point difference, F(1,1009) = 7.66, p = .006). In Study 2, conversely, there was no significant difference between Republicans and Democrats in trust of hyper-partisan sites (1.0 percentage point difference, F(1,1970) = 0.46, p = .497), and Republicans were significantly less trusting of fake news sites than Democrats (3.0 percentage point difference, F(1,1970) = 4.06, p = .044). Accordingly, there was a significant overall interaction between party and source type (p < .0001 for both studies).

Critically, however, despite these partisan differences, both Democrats and Republicans gave mainstream media sources substantially higher trust scores than either hyper-partisan sites or fake news sites (S1: F(1,1009) > 500, p < .0001 for all comparisons; S2: F(1,1970) > 180, p < .0001 for all comparisons). While these differences were significantly smaller for Republicans than Democrats (S1: F(1,1009) > 100, p < .0001 for all comparisons; S2: F(1,1970) > 80, p < .0001 for all comparisons), Republicans were still quite discerning. For example, they trusted mainstream media sources often seen as left-leaning, such as CNN, MSNBC, or the New York Times, to assess the reliability of news outlets. Second, news consumption patterns vary markedly across the political spectrum and it has been argued that political partisans are motivated consumers of misinformation (Kahan, 2017).
Times, more than well-known right-leaning hyper-partisan sites like Breitbart or Infowars.

When calculating an overall trust rating for each outlet by applying equal weights to Democratic-leaning and Republican-leaning participants (creating a “politically balanced” layperson rating that should reduce concerns regarding social media platforms having a partisan bias), every single mainstream media outlet received a higher score than every single hyper-partisan or fake news site (with the exception of Salon.com in Study 1). Additional analyses show that this remains true when restricting only to the most ideological participants in our sample, when considering only men versus women, and across different age ranges.

Furthermore, the politically balanced layperson ratings correlated highly with fact-checker ratings, $r(58) = .90, p < .0001$. Thus, we find remarkably high agreement between fact-checkers and laypeople. This agreement is largely driven by both laypeople and fact-checkers giving very low ratings to hyper-partisan and fake news sites: post hoc analyses show that, when only examining the 20 mainstream media sources, the correlation between the fact-checker ratings’ and the politically balanced ratings falls to $r(18) = .32$.

Analyses of the familiarity responses suggest that people are initially skeptical of news sources, and may come to trust an outlet only after becoming familiar with (and approving of) the coverage that outlet produces. As a result, familiarity is necessary but not sufficient for trust.

These observations provide evidence that crowdsourcing is a promising approach for identifying highly unreliable news sources, although not necessarily for differentiating between more or less reliable mainstream sources. Thus, having social media platforms algorithmically disfavor news sources with low crowdsourced trustworthiness ratings may – if implemented correctly – be quite effective in decreasing the amount of misinformation online.

SESSION OVERVIEW

Though consumer society has undergone rapid transformation over the past decades, for centuries storytelling and story consumption have remained a constant, defining feature of humanity. People enjoy and actively seek out stories. However, stories are not mere entertainment; they shape the beliefs and behaviors of those who consume them, including the understanding and transmission of wisdom. As noted in the 2019 ACR call for submissions, “Wisdom needs to be transmitted from communicator to listener, or author to reader. Storytelling is one way to accomplish this.”

This session focuses broadly on story consumption and its effects on consumers in general, and with reference to wisdom more specifically. The objective of the session is to illustrate individual consumer factors and narrative (message) factors that influence the experience of narrative consumption, as well as the downstream consequences of narrative consumption for consumers’ attitudes and behaviors. Consumer wisdom may be exercised before or during consumption (i.e., in selecting or navigating content in a wise or unwise fashion), or enhanced as a consequence of this process (i.e., transferring wisdom). Hamby, Tezer, and Escalas show that narrative content communicating meaningful or “wise” messages can evoke the audience response of eudaimonic pleasure (in contrast to the hedonic focus of a great deal of consumer narrative researcher), which has consequences for how readers value story-connected objects. Farmer and Nielsen also examine the influence of a narrative message factor on narrative consumption and responses, namely that of fear appeals. They show that stories featuring fear focus attention and enhance narrative transportation (Green and Brock 2000), a persuasive process which can facilitate the adoption of wise consumer attitudes. Wang and Escalas focus on a consumer characteristic that can influence how narratives are consumed: they show how the increasingly prevalent experience of consumer loneliness influences responses to narrative advertisements that feature a social appeal. Lonely consumers identify less with social appeals, and are less transported and influenced by the narrative. Finally, Feiereisen, Rasolofoarison, Russell and Schau focus on the experience of narrative consumption itself and broaden the traditional perspective to include factors related to the consumption environment. Specifically, they examine how individuals navigate narratives across time and space, and advance a theory of narrative navigation.

All of the papers included in this session expand our understanding of narrative consumption and influence beyond van Laer and colleagues’ (2014) model of narrative transportation: each of the papers addresses novel antecedents and consequences of narrative consumption, from a variety of methodological perspectives. In addition, each of the papers address the question of how narratives communicate or promote consumer wisdom and well-being, in keeping with the theme of the conference.

Story Symbols: How Meaningful Stories Enhance the Value of Story-Connected Objects

EXTENDED ABSTRACT

Can reading a fictional narrative about an object influence how much consumers are willing to pay for that object, despite awareness that the story is fictional? Moreover, does it depend on what the story is about? The current research examines how variation in narrative meaningfulness, an underexplored aspect of narrative content, leads to an increase in the valuation of an object depicted in a narrative. Drawing from self-determination theory (Ryan and Deci 2001), we define meaningful narrative content as that which communicates a message about relatedness, competence, and/or autonomy. In contrast to enjoyable content which may evoke hedonic pleasure, meaningful narrative content evokes eudaimonic pleasure, which is associated with significance, self-realization, and broader well-being (Oliver and Raney 2011; Ryan and Deci 2001).

We show that meaningful (vs. simply enjoyable) narrative content enhances the valuation of objects that are central to the narrative plot, and this occurs because the eudaimonic pleasure evoked by meaningful narrative content transforms the object depicted in the story into a symbol of the meaning derived from the narrative (a serial mediation process). We assert that this process occurs separately from the hedonic affect transfer process shown in consumer research on narrative transportation to date (e.g. van Laer et al. 2014). Narrative transportation, the extent to which the reader is immersed in a narrative, is characterized by emotional engagement, generation of mental imagery, and allocation of attention to the narrative world events, and is an inherently enjoyable process (Escalas 2007; Green and Brock 2000), and has been examined as the primary mechanism in narrative persuasion.

Overall, the current work makes three main contributions to consumer research on narrative consumption: First, we identify and define meaningful narrative content as an influential dimension of a narrative, building on prior consumer research on narratives (Escalas 2007; Van Laer et al. 2014). Second, we link meaningful narrative content to eudaimonic pleasure and demonstrate its influence on consumers’ valuation of an object, providing a complementary perspective to consumer research that examines hedonic pleasure (Hirschman and Holbrook 1982). Third, we illustrate the role of eudaimonic pleasure as a value and symbol-creation mechanism, connecting narrative persuasion research to literature which describes how symbols obtain their meanings (i.e., McCracken 1989; Mick 1986).
We accomplish this across five studies. In the first two studies (1A and 1B), we examine the influence of eudaimonic pleasure on the valuation of objects. In study 1A we demonstrate that eudaimonic pleasure is a result of narrative transportation into a meaningful story, and it subsequently influences object valuation by ascribing the object with symbolic meaning ($\beta > .18, p < .01; \beta = .03, SE = .01, 95\% CI = .02, .04$). We also replicate (and control for) the existence of a hedonic path, in which transportation influences hedonic pleasure, positive affect, which also enhances object valuation ($\beta > .17, p < .01; \beta = .02, SE = .01, 95\% CI = .01, .03$). In study 1B, we manipulate the meaningfulness of narrative content (high vs. low) to distinguish the role of eudaimonic pleasure on object valuation, and replicate the results of study 1A: we show that participants in the meaningful narrative condition valued the object more ($M = 4.35, SD = 1.23$) than those in the simply entertaining narrative condition ($M = 3.37, SD = .95; F(1, 94) = 18.93, p < .001$). In addition, participants state more interest in purchasing raffle tickets to win an object associated with the meaningful ($M = 4.35, SD = 1.23$; versus entertaining; $M = 3.37, SD = .95$) story ($F(1,94) = 4.51, p < .05$).

Study 2 exposes consumers to a meaningful story and manipulates cognitive load to prevent narrative transportation, thus reducing eudaimonic pleasure and symbolic meaning transfer. The results revealed that participants in the low cognitive load condition ($M = 5.23, SD = 1.02$) had higher evaluation of the object compared to those in high cognitive load condition ($M = 4.87, SD = 1.02; F(1,100) = 3.85, p = .048$), and the indirect effects suggest that this occurs through suppressing the eudaimonic pleasure experienced ($\beta = .05, SE = .03, 95\% CI = .01, .12$). Together, these first three studies demonstrate that meaningful content evokes transportation and eudaimonic pleasure, which enhances object valuation because the objects become symbols of the meaning conveyed by the narrative.

Studies 3 and 4 explore boundary conditions. Study 3 shows that the positive effect of meaningful narrative content on the valuation of the object featured in the narrative is conditioned on the centrality of the object to the narrative plot: We conducted a repeated measures ANOVA on the willingness to pay for objects central and peripheral to a narrative plot as a within-subjects factor, and included narrative content (meaningful vs. simply entertaining) as a between-subjects factor. Tests of within-subjects effects revealed a main effect of object ($F(1, 86) = 44.83, p < .001, \eta^2 = .343$) such that the plot-central object evoked overall higher willingness to pay ($M = 2.73, SD = 1.87$) than the peripheral object ($M = 1.51, SD = 1.31$). Study 4 adopts a 2 (narrative content: meaningful, entertaining) x 2 (purchase: for self, as gift) design to test a second boundary condition of the target for purchase. In the meaningful narrative condition, the object was valued more when the participants imagined purchasing it for the self ($M = 3.26, SD = 1.29$) relative to purchasing it as a gift, where the story is not included ($M = 2.59, SD = .92; F(1,187) = 7.92, p = .005, \eta^2 = .041$). In the entertaining narrative condition, the effect of purchase context reversed (Purchase as gift: $M = 3.17, SD = 1.30$; Purchase for self: $M = 2.74, SD = 1.10; F(1,187) = 3.12, p = .08, \eta^2 = .016$). Study 4 provides further process evidence of the proposed model with moderated serial mediated. Our results underscore the richness in the ways that stories create value for consumers, and how this value comes to be captured in objects.

**Walk a Mile in Someone Else’s Relationships:**

**How Loneliness Affects Narrative Processing of Social Ads**

**EXTENDED ABSTRACT**

One of the most fundamental human needs is the need for social relationships (Baumeister and Leary 1995). Hence loneliness, the subjective feeling of social isolation, has a significant impact on consumers (Cacioppo et al. 2002; Baumeister, Twenge, and Nuss 2002). And the problem of loneliness is growing: screen time on tech devices is significantly related to an increase in felt loneliness and a decrease in life satisfaction (Stepanikova, Nie, and He 2010). Consumer researchers have examined various consequences of loneliness such as product endorsement (Wang, Zhu and Shiv 2012) and impulsive consumption (Sinha and Wang 2013). Here, we explore another important, understudied consequence of loneliness—how lonely consumers process narratives.

A large number of marketing communications take the form of narratives, often depicting some form of social interaction between characters. The narrative literature suggests that stories persuade via the experience of transportation—the feeling of being caught up or “lost” in the narrative. In order to experience transportation, the audience often identifies with the characters, takes their perspectives, and empathizes with them. Thus, narrative persuasion depends on how individuals relate to and identify with story characters and their interpersonal relationships.

Extant research on loneliness shows that it disrupts individuals’ executive control, attention, and self-regulation (Campbell et al. 2006; Wondra and Ellsworth 2015), all of which are critical for them to identify with others (Jackson, Meltzoff, and Decety 2005). Indeed, Cacioppo et al. (2009) found that when looking at pictures of people in peril, activation of the temporoparietal junction, an area involved in perspective taking, was weaker among lonely participants. Therefore, existing research suggests that lonely people are less likely to identify and emphasize with others.

In this research, we investigate how loneliness affects consumers’ transportation into marketing narratives, depending on their social nature. We predict that lonely people will have difficulty identifying with characters engaged in social interactions in marketing narratives, reducing the likelihood that they become transported and persuaded by the ad. Alternatively, narratives about a person using a product alone will not affect the likelihood that lonely and non-lonely consumers are transported and persuaded. We tested our hypotheses across five studies.

Study 1A measured participants’ felt loneliness and their transportation into and attitudinal responses toward a social narrative storyboard ad. We also measured a number of plausible confounds such as need to belong, depression, affect intensity. We found that lonely participants were less transported into the ad ($\beta = -.22, p < .01$) and had less favorable attitudes toward the ad and the product ($\beta = -.014, p = .05$). Mediation analysis showed that the effect of loneliness on attitude was mediated by ad transportation. Similar regression analyses with need to belong, depression, affect intensity indices ruled them out as alternative explanations.

Study 1B measured participants’ loneliness and exposed them to a different social narrative ad featuring pretzel snacks. They then chose one of five different kinds of snacks from a vending machine located in the lab (without charge). On average, 11% of participants chose the pretzel snack from the vending machine. As participants became lonelier, they were marginally less likely to choose pretzels after seeing the socially focused, narrative pretzel ad (Wald’s $c^2 =$
Study 2 manipulated the extent to which the narrative focuses on social relationships by changing some pictures and text. With a different product category, we found significant interactions of loneliness and ad focus on transportation ($\beta = .21, p < .05$) and attitudes ($\beta = .018, p = .06$). Lonely (vs. non-lonely) participants were less transported into the social ad ($\beta = -.35, p < .01$) and had less favorable attitudes ($\beta = -.03, p < .01$). However, participants’ transportation into ($\beta = .74, p > .60$) and attitudes toward ($\beta = .002, p > .90$) the non-social ad did not vary by loneliness. We found a significant moderated mediation: transportation mediated the effect of loneliness and ad focus on attitude for the social ad, but not for the non-social ad.

Study 3 manipulated both participants’ loneliness and the social focus of the narrative. Participants first wrote about a lonely or socially connected experience, and then responded to either a social ad or a non-social ad. We found significant interactions on transportation ($F(1, 131) = 5.55; p < .05$) and attitudes ($F(1, 131) = 5.06; p < .05$). Lonely (vs. non-lonely) participants were less transported into the social ad ($48.43 vs. 54.04, t = -2.09; p < .05$) and had less favorable attitudes ($4.18 vs. 4.56, t = -1.69; p = .09$). However, lonely (vs. non-lonely) participants were equally transported into the non-social ad ($52.53 vs. 48.54, t = 1.4; p > .10$) and had equally favorable attitudes ($4.47 vs. 4.04, t = 1.61; p > .10$). We found a significant moderated mediation: transportation mediated the effect of loneliness on attitude for the social ad, but not for the non-social ad.

Study 4 explored the process underlying these effects by manipulating the protagonist of a socially focused narrative ad: either a third person character, or second person “You.” Loneliness was measured. We found significant interactions of loneliness and ad focus on transportation ($t = 2.76, p < .01$) and attitudes ($t = 2.56, p = .01$). Lonely (vs. non-lonely) participants were less transported into the 3rd person ad ($-38, t = -2.76, p < .01$) and had less favorable attitudes ($-034, t = -2.65, p < .01$). However, participants’ responses to the 2nd person ad did not vary by their felt loneliness for either transportation ($-16, t = 1.17, p > .24$) or attitudes ($-01, t = .99, p > .30$). We found a significant moderated mediation: transportation mediated the effect of loneliness on attitude for the third-person ad, but not for the “You” ad.

Together, these studies demonstrate that lonely consumers are not transported into or persuaded by narrative advertisements that highlight social relationships for characters other than themselves.

**Navigating Narratives: Time and Space Navigation and Narrative Experiences**

**EXTENDED ABSTRACT**

Consumers engage with a wide range of narratives, including books, comics, movies and TV series. Extant work has shown that cultural producers are increasingly telling single stories across multiple platforms and formats via a process of transmedia storytelling (Illhan, Otnes and Kozinets 2013; Jenkins 2006; Scolari 2009) and that interpretive communities (Fish 1980; Schau and Muñiz 2004) co-produce narrative materials. Despite the noteworthy contributions of these studies, we still know little about the ways consumers navigate narratives and about how consumers experience narratives when many additional transmedia narratives are available.

In developing a comprehensive theory of narrative consumption, we attempt to reconcile theories that have positioned the consumer as an immersed (often sole) ‘reader’ who becomes “lost” in a story via narrative transportation into that story (Green and Brock 2000, p. 702) and theories that embrace the co-creative power of consumers in actively shaping the meaning of narratives (Chronis 2008; Stern 1989), and forming active communities of interpretation around narrative brands (Kozinets 1997, 2001; Parmentier and Fischer 2014; Russell and Schau 2013). We also draw on the reading literature, in particular the needs and gratifications derived from reading for pleasure, along with the notion that readers control the pace at which they read books, either savoring them or instead behaving like “gluttonous” readers (Nell 1988, p. 42). Furthermore, we conceptualize narrative navigation as a form of intertextual navigation, building on the literature on intertextuality which views the text as the site of a complex interaction between different texts that together form a textual system (Kristeva 1969).

This study uses an interpretive research strategy. Informants are consumers who regularly watch TV series. These informants provided insights through 21 in-depth interviews. Sixteen of these informants completed a diary over a period of two weeks prior to the in-depth interview. These data were supplemented by forum thread analysis of The Big Bang Theory, Game of Thrones and Westworld with 103 threads selected for popularity and relevance to intertextuality, character discussion and viewing cadence and 51,235 messages. Finally, we conducted video-recorded ethnographies of TV series viewers’ behavior (Jayasinghe and Ritson 2013) with member check interviews. The video-recorded ethnographies were conducted with 11 informants (5 couples and one single informant) who reported watching TV series very regularly. These video-recorded ethnographies were vital to deepening our understanding of the navigational movements consumers use when watching TV series alone or with others.

Our findings highlight the dynamics of how consumers navigate narrative time and narrative space. Consumers may navigate the narrative in a linear manner, whereby they do not modify the pace of the narrative. Furthermore, many of our informants navigate time to either decelerate narrative pace (e.g., by spacing out viewing between episodes) or accelerate narrative pace via binge-watching (i.e., the practice of watching multiple episodes of a television program in rapid succession). However, in contrast with the readers in Nell (1988), some of our informants may lose temporal control and experience guilt after binge-watching. In addition, TV series viewers may engage in temporal augmentation to increase the time they spend consuming the narrative (e.g., by replaying scenes or episodes). Beyond time navigation, consumers may engage in space navigation, either by contracting narrative space (e.g., skipping scenes or even episodes), which also accelerates narrative pace, or by expanding from the primary space of the narrative to other spaces, such as the transmedia space (e.g., by reading online summaries of the episodes), the social space (e.g., by discussing the series with peers) or the mental space (e.g., by spending time pondering what will happen next in the series). Interestingly, we note instances of interactive dynamics where consumers engage in space expansion while shortening the time they spend consuming the narrative. We then explore the driving factors of narrative navigations. Specifically, when and why might consumers prize different types of time and space navigations? We unwrap three drivers of narrative navigations: (1) the text’s gravitational pull, which includes narrative density, closure and pace, (2) consumers’ relationships to time and space and (3) the social context and interpretive communities. Several narrative experiences arise from the time and space navigations we observed. Particularly noteworthy is that distinct narrative navigational movements may lead to the same narrative experience. Furthermore, the same navigational endeavors may lead to different narrative experiences. For example, two of our informants, Leonard and Penny, both report reading online summaries of the episodes of...
the series that they follow and then watching selected scenes only, thereby expanding into the transmedia space but shortening the time they spend consuming the narrative. However, their narrative experiences are entirely different as they have different aims for engaging in this narrative navigation: Leonard’s aim is to save time whereas Penny strives to remove any uncertainty and suspense associated with the storyline. While these consumers do not create their own fan fiction as in extant work by Schau and Muñiz (2004) and Jenkins (2012), they do bear similarities with these fans as they reframe the series’ narrative to suit their needs and express their own desires by skipping the content they do not wish to see. This finding adds to the literature on the tension between corporate and consumer control (Kates 1997), as we find that consumers reject parts of the narrative.

This research puts forward a theory of narrative navigation. The study reveals how consumers navigate narrative time and space, when and why they may prize certain narratives over others and the distinct ways in which they experience narratives beyond narrative transportation. Although digital tools and technologies render navigation across spaces faster and more synergistic, the dynamic experiences we uncover do not seem bound to digital media narrative consumption. We discuss the implications of our findings for narrative theory, along with theories of transmedia storytelling and interpretive communities.

Moved by Scary Stories: How Fear Drives Narrative Transportation

EXTENDED ABSTRACT

Public health advocates use emotional narratives to warn consumers about dangerous behaviors like distracted driving. While we still do not fully understand if and how fearful narratives persuade consumers, research has found that people who consume a captivating story can reach a state of immersion known as narrative transportation that leads to the adoption of story-based beliefs, attitudes, and intentions by reducing counterarguing against the narrative’s message (Green and Brock 2000; van Laer et al. 2014). Despite the widespread use of emotional narratives, emotions have played a surprisingly small role in narrative transportation research (c.f., Escalas 2004). Because fear is commonly used in narrative persuasion, it is important to understand how fear affects known narrative transportation processes. We draw on existing models of fear and apply them to the narrative transportation model to predict that fear drives narrative transportation through an increase in attentional focus. We also show that this increase in narrative transportation makes fearful narratives more persuasive by reducing counterarguing.

Extant literature does not currently yield clear predictions about how fear will impact the narrative transportation process. On the one hand, fear can cause consumers to avoid or otherwise resist a potentially threatening message (e.g., Janis and Feshbach 1953; Janis and Terrorsiller 1962), which would inhibit the attentional resources required for transportation to occur (Green and Brock 2000; Nielsen and Escalas 2010). For example, a scary distracted driving advertisement may be so intense that it causes consumers to focus on other objects in their environment or even change the channel. On the other hand, fear can increase attentional focus toward threatening stimuli (Coleman et al. 2017; Pratto and John 1991), which would enhance the attentional resources that drive narrative transportation. If this were the case, a scary distracted driving advertisement would cause consumers to instead tune out distractions and attentively watch the entire advertisement. Recent research has suggested that the latter response, in which fear drives increased attention toward the narrative, is more likely if consumers feel like they can respond to the threat presented by the fearful message (i.e., by turning their phones off while driving; see Basil and Witte 2014). Thus, we posit that fearful narratives will increase attention toward the narrative and boost narrative transportation, which in turn will more effectively persuade consumers by reducing counterarguing.

In all studies, participants saw narrative ads in the form of storyboards (Escalas 2004; Nielsen and Escalas 2010) aimed at curbing distracted driving. Depending on the condition, these narratives were either neutral or fear evoking and were always followed by a measure of narrative transportation (Green and Brock 2000).

In study 1, we randomly assigned 234 participants to watch either a neutral or fearful version of the storyboard for a public service announcement titled “It Can Wait”. Participants then completed three 9-point scales: the narrative transportation scale (Green and Brock 2000), a scale to measure counterarguing (Nabi, Moyer-Gusé, and Byrne 2007), and a persuasion scale that we developed (α=.84; e.g., “Do you consider distracted driving to be more of a concern after viewing the message?”). Results confirmed that participants who viewed the fearful version of the PSA indicated increased transportation (M_{neutral}=5.63, M_{fearful}=6.25, F(1,233)=13.48, p < .001) and persuasion (M_{neutral}=5.41, M_{fearful}=6.59, F(1,233)=32.60, p < .001), and decreased counterarguing (M_{fearful}=2.61, M_{neutral}=3.27, F(1,233)=15.24, p < .001). The results confirm that the direct effect of fear on persuasion was mediated first by an increase in transportation and then by a decrease in counterarguing (β=.04, 95% CI [.01, .10], PROCESS model 6, Hayes 2009).

Study 2 was designed to more directly test the role of fear as a driver of transportation by introducing incidental fear prior to the narrative. We randomly assigned 195 students to either write about a time in their life when they were really scared (fear condition) or a place with which they were familiar (control condition; Passyn and Sujan 2006). Participants then watched the neutral PSA used in study 1. Analysis revealed that the fearful condition led to higher transportation into the subsequent PSA than the neutral condition (M_{neutral}Prime=5.70, M_{fearPrime}=6.21, F(1,194)=7.84, p < .01).

To further demonstrate that fear is a driver of transportation, study 3 introduced a fear-evoking message either very early or very late in the narrative. In other words, the fearful content and PSA were held constant between conditions; only their order was manipulated. Results confirmed that those who saw the fear evoking message before (vs. after) the storyboard images experienced higher transportation (M_{fearBeginning}=6.37, M_{fearEnd}=5.94, F(1,195)=4.25, p=.041) and persuasion (M_{fearBeginning}=6.74, M_{fearEnd}=6.22, F(1,195)=4.18, p=.042) by the “don’t text and drive” message. Transportation mediated the effect of the fearful stimulus order manipulation on persuasion (IE = .34, 95% CI [.01, .69]).

Studies 4a and 4b established evidence that attention is responsible for the effect of fear on narrative transportation. In study 4a, we replicated study 2 by manipulating fear and showing the same PSA storyboard, but with a series of symbols at the outer edge. Those in the fearful (vs. neutral) condition noticed fewer of these symbols on the edge of the screen (M_{fearPrime}=2.69, M_{neutralPrime}=2.26, F(1,149)=4.07, p=.045) while still passing two attention check questions, demonstrating that they paid more attention to the narrative. In study 4b, we randomly assigned participants to one of two versions of the PSA: one in which the storyboard was surrounded by a blank white screen (control condition) and one in which the storyboard was surrounded by several pictures and links that changed every five seconds (distraction condition). Those in the distraction condition were less transported by the narrative storyboard than those in the control condition (M_{Distraction}=6.00, M_{control}=6.42, F(1,193)=3.72, p=.055). Together, these studies provide initial evidence that fear
boosts narrative transportation by increasing focused attention toward the narrative. Narratives frequently elicit emotional responses in consumers, and those responses are not always positive. The current research investigates one important context in which the responses to narratives are not expected to result in positive affect (i.e., fear appeals) and explores how fear can drive more narrative transportation and, consequently, more persuasion.

Public health advocates often use narratives to warn consumers about the dangers of certain behaviors, such as texting and driving. However, we still understand relatively little about how narratives that elicit negative emotions persuade consumers. In the current work, we find that fear arousal increases focused attention toward the narrative, which in turn boosts narrative transportation and augments the persuasive power of the advertisement by reducing counterarguing against the message. This work enhances our understanding of how narratives that elicit negative emotions can persuade consumers and also contributes to research on narrative transportation by showing how negative emotions can work as antecedents to narrative transportation.

REFERENCES
Fish, Stanley Eugene (1980), Is there a Text in this Class? The Authority of Interpretive Communities, Harvard University Press.

The third paper by Uqlinaku, Sarial-Abi, and Inman studies how consumers use brands to cope with negative self-conscious emotions. The authors show that individuals with self-esteem threats prefer fighter brands, and individuals with social exclusion threats prefer caregiver brands. Additionally, they found that these brands help individuals engage in problem-focused (i.e., the fighter brand) or emotion-focused (i.e., the caregiver brand) coping to mitigate the effects of these psychological threats.

The last paper by Rocklage and Luttrell shifts gears and focuses on the effect of emotion on attitude stability. The authors found that whereas some consumer attitudes are fixed, others are fleeting. Across six longitudinal studies and linguistic analysis of 80,000 Yelp reviews, the authors found that the more an attitude was based on emotion, the longer-lasting that attitude. Moreover, consumers appear unaware of this connection.

Together, employing different research methods, these four papers present distinct yet synergistic findings that further our understanding of consumers’ emotional lives. The topics of the four papers are fundamental to consumers’ everyday lives, and this special topic session should be of great interest not only to marketing researchers, but also to anyone who is interested in the factors and strategies that can improve our understanding and management of consumer emotions.

The Self-Conscious Consumer: Understanding and Mitigating Consumer Embarrassment

EXTENDED ABSTRACT

Previous research distinguishes between more spontaneous, hedonic emotions and more deliberative, self-conscious emotions (Giner-Sorolla 2001; Leary 2007). Hedonic emotions, such as excitement, joy, and sadness, are immediate in nature and elicited spontaneously without much cognitive elaboration. In contrast, self-conscious emotions, such as embarrassment, guilt, pride, and shame, are more deliberative in nature (Leary 2007). They are characterized by an awareness of the emotional state, cognitive elaboration, and self-reflection (Pham et al. 2001).

Embarrassment, in particular, is a pervasive emotion in the marketplace. People can go to great lengths to avoid feeling embarrassed or can engage in compensatory behavior to cope with embarrassment (Miller 1996). While researchers and practitioners alike recognize the adverse implications of embarrassment in consumption, research on embarrassment is still surprisingly sparse in the consumer psychology literatures (Krishna et al. 2019). Across three studies, we examine how cognitive resources and deliberation influence self-appraisal and resulting embarrassment, and suggest strategies for marketers to mitigate or manage consumer embarrassment.

In the first study (N = 203, 46.5% female; M_age = 37.5), we test whether encouraging consumers to deliberate on their experience increases embarrassment. We also examine a managerially relevant dependent variable: likelihood to recommend a product. We used a 2 x 2 between-subjects design with product (embarrassing vs. not embarrassing) and deliberation (high vs. low) as the two independent factors. Participants were told to imagine searching for and purchasing a hair regrowth treatment or a shampoo. Those in the deliberation condition were also instructed to take a moment to think about the scenario and elaborate on what they would be thinking (Gale et al. 2007).
Next, all participants reported the intensity of embarrassment they would feel if they personally had this experience (embarrassed, uncomfortable, and ridiculous; Krishna et al. 2015; α = .95) and their recommendation likelihood. Across all studies we included gender and familiarity as covariates consistent with prior research, (Dahl et al. 2001). Five participants were removed due to reading checks.

An ANCOVA with embarrassment as the dependent variable showed a significant main effect for product \( F(1, 192) = 38.44; \ p < .001 \), a non-significant effect of deliberation \( F < 1 \) and a significant interaction \( F(1, 192) = 4.11; \ p < .05 \). For the embarrassing product purchase scenario, participants reported greater embarrassment when they deliberated \( M_{\text{Embarrassing, High Deliberation}} = 3.60 \), \( M_{\text{Embarrassing, Low Deliberation}} = 2.89; \ p < .05 \); however, there was no difference for the non-embarrassing product purchase \( F < 1 \). An ANCOVA with recommendation likelihood revealed a similar effect, with participants seeing the embarrassing product less likely to recommend when they had deliberated \( M_{\text{Embarrassing, High Deliberation}} = 3.63 \), \( M_{\text{Embarrassing, Low Deliberation}} = 4.62; \ p < .05 \), but showing no difference for the non-embarrassing product \( F < 1 \).

Per our conceptualization, embarrassment ensues following deliberation and self-appraisal in relation to a trigger incident. Therefore, limiting cognitive resources should lower self-appraisal, and ultimately, felt embarrassment. We tested this proposition in a second study \( N = 214 \), 45% female; \( M_{\text{Age}} = 24.2 \), using a 2 x 2 between-subjects design with product (embarrassing vs. not embarrassing) and cognitive load (high vs. low) as the two independent factors. Participants were involved in a purchase scenario similar to study 1 with a new set of products (incontinence vs. headache medication). Cognitive load was manipulated with an external memory task (Gilbert et al. 1995). We used the same embarrassment scale as in study 1; and also collected a 2-item measure of the extent to which participants consciously engaged in self-appraisal (e.g., “I would judge myself for this action”; \( r = .85; \ p < .01 \)). In addition to gender and familiarity, we also included measures of need for cognition due to the cognitive nature of the task. Four participants were removed due to reading checks.

An ANCOVA with embarrassment as the dependent variable showed a significant main effect for product \( F(1, 203) = 85.47; \ p < .01 \). The main effect of cognitive load and effects including gender were not significant \( (p's > .1) \). The two-way interaction between product and cognitive load was significant \( F(1, 203) = 6.54; \ p < .05 \). Participants reported lower embarrassment under high (vs. low) cognitive load when purchasing the embarrassing product \( M_{\text{Embarrassing-Low Load}} = 4.67 \), \( M_{\text{Embarrassing-High Load}} = 4.01; \ F(1, 203) = 6.73; \ p < .05 \). However, there was no difference between the load conditions for the non-embarrassing product purchase \( F > .3 \). We then tested the full moderated mediation model with Hayes’ (2013) PROCESS macro with self-appraisal as the proposed mediator. As expected, we found a significant indirect effect of cognitive load on embarrassment through self-appraisal only when purchasing an embarrassing product \( (CI: -.014 \text{ to } -.64) \), and not when the product was non-embarrassing \( (CI: -.06 \text{ to } .45) \).

In study 3, we tested whether the choice task itself could act as a mental distraction when appraising a potentially embarrassing experience. Study 3 \( N = 182 \), 40.3% female; \( M_{\text{Age}} = 40.03 \) utilized one-way design of choice complexity (simple/dominant choice vs. simple/non-dominant choice vs. complex/non-dominant choice). We predicted that the more complex task would result in greater embarrassment. After indicating their product choice, participants completed the embarrassment and control measures. Three participants were removed due to reading checks.

An ANCOVA with embarrassment as the dependent variable showed a significant main effect for complexity \( F(1,173) = 3.89; \ p < .05 \). Participants in both the simple/non-dominant \( (M = 3.18; \ t(1,173) = 1.96; \ p < .05 \), and the complex/non-dominant choice conditions \( (M = 2.96; \ t(1,173) = 2.73; \ p < .01 \) reported lower embarrassment compared to participants who saw the dominant superior option \( M = 3.86 \). These results showed support for our prediction that a mentally taxing evaluation process lowered cognitive resources and resulted in lower embarrassment.

Embarrassment is clearly an important emotion to understand, with much impact on everyday motivations and consumer behavior. Our work integrates extant research from psychology and more recent work from consumer behavior to better understand the processes triggering consumer embarrassment. Our results demonstrate ways of mitigating the negative consequences of consumer embarrassment through constraining deliberation on the experience, without losing from careful product evaluation.
checkout. We also expect shoppers’ preference for human checkout when buying organic products to attenuate when they have larger baskets, because the salience of the organic item(s) would decline with a larger basket.

To test our hypotheses, we analyzed a panel dataset from a supermarket chain with both human checkout and self-service checkout counters. This dataset includes seven weeks of receipt-level transaction information at three different stores, with a total of 223,585 transactions. We found that baskets with embarrassing products contained on average 0.7 more items ($M = 5.01, SD = 6.59$, excluding the embarrassing item(s)) than non-embarrassing baskets ($M = 4.32, SD = 5.14, t(223,580) = 2.21, p = .02685$). This result is consistent with past research showing that consumers buy more items to cover up their purchase of embarrassing products (Brackett 2004; Lewittes and Simmons 1975).

Next, we conducted logistic regressions with the choice between self-service checkout and human checkout as the dependent variable. We focused our analysis on transactions paid with credit or debit cards (126,144 transactions) because the self-service checkout machines could not accept cash. The key predictors included whether a basket contained condoms (an embarrassment dummy = 1 for baskets containing condoms, and = 0 otherwise). Further, the choice of checkout counters could also be driven by convenience (human cashier provides service) and time-saving (due to store traffic) considerations; therefore, we controlled for these and other competing factors. Thus, we included control variables such as the week, the day of the week, the hour, the store, whether a membership card was swipe, the number of open human counters at the time of the transaction, and basket size.

Our model also included a threshold dummy for salience—the number of items in a shopping basket beyond which our proposed effects of condom or organic purchases are no longer observed. The dummy was coded as 1 when the basket size was smaller than the threshold, and 0 otherwise. To determine the threshold, we varied the threshold from 1 to 10 and picked the value (five) that offered the best fit to the data.

The logistic regression using five as the threshold reveals that for baskets with condoms, shoppers were more likely to select self-service checkout compared to those who did not purchase condoms, such that the odds of choosing self-service checkout was about 1.81 times higher if a shopper bought condoms than if s/he did not buy condoms ($b = 0.5943$, $t = 2.3527, p = .0186$). When the baskets with condoms contained five or more items, the effect of buying condom was significantly reduced ($b = -1.0799$, $t = -3.1067, p = .0019$).

Using whether a basket contained organic products (a positive-image dummy = 1 for baskets containing organic products, and = 0 otherwise) as the key predictor, we found that shoppers with one or more organic products in their baskets were less likely to choose self-service checkout compared with shoppers who did not buy any organic products ($b = -1.1748$, $t = -3.5251, p = .0004$, odds ratio was only 0.84 times of the odds ratio for purchases not including organic items). However, this preference for human checkout (vs. self-service checkout) was reduced when the baskets contained five or more items ($b = .1491$, $t = 2.4303, p = .0151$), mirroring the results for baskets containing condoms. This pattern is consistent with our argument that with a larger basket, the organic product(s) would be less salient and thus less likely to communicate a positive image, resulting in shoppers’ lower motivation to “show off.”

Taken together, our results suggest that self-conscious emotions can exert powerful influences on shopping behavior. Our findings have rich implications for marketing practitioners regarding store-space planning, self-service technology design, product packaging (e.g., conspicuousness of the enclosed item), and service-process design.

### The Fighter and the Caregiver: Brands that Help Individuals with Self-Esteem and Social Exclusion Threats

#### EXTENDED ABSTRACT

Over the last 20 years, top journals in marketing and psychology have published approximately 800 articles on self-esteem (the fear of not being up to one’s expectations) and social exclusion (the fear of being socially impaired) threats, establishing the importance of research on this topic. In this paper, we investigate how brands can mitigate these threats.

When self-esteem is threatened, individuals activate a problem-focused coping strategy to mitigate the effects of self-esteem threats (Han, Duhachek, and Rucker 2015). They need someone to fight for them (but not emotionally take care of them; Strelan and Zdaniuk 2015), to combat, to positively change the situation. In a branding context, a fighter brand would be one with a strong sense of justice and loyalty, who is ready to fight for consumers’ rights (Hartwell and Chen 2012). In this paper, we expect a fighter brand to mitigate the effects of self-esteem threats:

**Hypothesis 1a** Individuals exposed to self-esteem threats (vs. social exclusion, no-threat) prefer fighter brands.

**Hypothesis 1b** The effect of self-esteem threat on preference for fighter brands is mediated by problem-focused coping.

When individuals experience social exclusion threats, a “caregiving emptiness” is created (Twenge et al. 2007). Consequently, individuals use emotional-coping strategies to cope with social exclusion threats (Han et al. 2015). These individuals need support from others to cope with social exclusion. They need to rely on things that can provide care to them. A person experiencing social exclusion is less likely to approach others or fight and would typically expect a caregiver to provide social support (MacDonald and Leary 2005). In a branding context, a caregiver brand would be one taking care for the consumer, nurturing her, or her wellbeing. In this paper, we expect a caregiver brand to mitigate the effects of social exclusion:

**Hypothesis 2a** Individuals who experience social exclusion threat (vs. self-esteem threat, no-threat) prefer caregiver brands.

**Hypothesis 2b** The effect of social exclusion threat on preference for caregiver brands is mediated by emotion-focused coping.

In study 1, we investigated the kind of brands individuals prefer when they are threatened. Initially, we asked participants to think of an event that made them feel psychologically threatened (social exclusion and/or low self-esteem). Next, we asked them to think of an event that made them feel psychologically threatened. We then asked participants to rank their feeling after each event on a scale. Finally, we asked them to think of an event that made them feel psychologically threatened.

In study 2, we investigated the kind of brands individuals prefer when they are threatened. Initially, we asked participants to think of an event that made them feel psychologically threatened (social exclusion and/or low self-esteem). Next, we asked them to think of a brand that would provide them some kind of psychological relief. We then asked the participants to rank their feeling after each event on a scale. Finally, we asked them to think of an event that made them feel psychologically threatened.
In study 2, we tested H1a and H2a, in a behavioral experiment using real choice situation. Participants were first randomly assigned to self-esteem threat, social exclusion threat, or no threat.

We next told participants that we would like to offer them a pack of tea bags as a reward for their participation, among four new brands: Brand A (positioned as a caregiver), Brand B (positioned as a fighter) and Brand C (mix) and D (none), used as control. We then asked participants to choose one tea bag to take with them.

As predicted, when individuals experienced self-esteem threats, they chose a fighter brand (53.33%) more than a caregiver brand (13.33%; z = 6.44, p < .001), or control brands (mix: 23.33%; z = 3.89, p < .001; none: 10.00%; z = 7.91, p < .001). Individuals who experienced social exclusion threat chose the caregiver brand (54.84%) more than the fighter brand (19.35%; z = 5, p < .001), or control brands (mix: 19.35%; z = 5, p = .007; none: 6.45%; z = 10.97, p < .001).

In study 3, we tested all hypotheses together. We used a 2 (threat: self-esteem, social exclusion) by 2 (brand: fighter, caregiver) between-subjects design. We next measured the problem-focused and emotion-focused coping scale (Han et al. 2015). Participants were then introduced to a separate study where they indicated their brand preference.

As predicted, when participants were exposed to social exclusion threats, they preferred more caregiver brands ($M_{social-exclusion-caregiver} = 4.355, SD_{social-exclusion-caregiver} = .717$; $M_{social-exclusion-fighter} = 3.732, SD_{social-exclusion-fighter} = 1.078$; $t = 2.606, p = .013$). Analogously, when participants were exposed to self-esteem threat, they preferred more fighter brands ($M_{self-esteem-fighter} = 4.283, SD_{self-esteem-fighter} = .906$ vs. $M_{self-esteem-caregiver} = 3.648, SD_{self-esteem-caregiver} = .897$; $t = 2.606, p = .01$).

The mediation analysis results showed a significant effect (CI: 95% = [.062; .414]) of emotion-focused coping on brand preference, moderated by brand positioning as caregiver. Moreover, the mediation analysis results showed a significant effect but only at the 90% level of confidence (CI: 90% = [.097; .492]) of problem-focused coping on brand preference, moderated by brand positioning as fighter.

In study 4, we tested all the hypotheses together, using real consumption. We used a 2 (threat: self-esteem threat, social exclusion threat condition as in study 3) by 2 (brand: fit, non-fit, adapted from study 3) between-subjects design. After being exposed to the threat, participants were asked to consume at least 250 ml of tea (as a separate market test). In the fit brand condition, they received a communication that described the brand as a caregiver (vs. fighter or control) if exposed to social exclusion threat, or a communication that described the brand as a fighter (vs. caregiver or control) if exposed to self-esteem threat. Next, participants completed the problem-focused and emotion-focused coping scale on how they would have dealt with the threatening situation they described before now (i.e., after the consumption).

As predicted, there was an interaction of the effect of threat (self-esteem vs. social exclusion) and brand positioning (fit, non-fit) on ratings for emotion-focused coping ($F(1, 111) = 4.951, p = .003$) and for problem-focused coping ($F(1, 111) = 4.321, p = .04$).

In this paper, we provide convergent evidence that individuals prefer, express more positive attitudes, and choose different types of brands (i.e., fighter or caregiver) depending on the psychological threat (i.e., social exclusion or self-esteem) they experience.

Attitudes Based on Feelings: Fixed or Fleeting?

EXTENDED ABSTRACT

Companies measure consumers’ opinions so as to predict consumers’ judgments and behavior in the future. This is based on the assumption that the attitudes consumers express at any given time are at all related to their attitudes when making future judgments or purchasing decisions. Indeed, attitudes are often presumed to be relatively consistent across time and the very definition of an attitude is an evaluation that is stored in memory, and therefore relatively long-lasting (Fazio 2007). Despite this assumption, research indicates that whereas some attitudes are fixed, others are as fleeting as the time it takes consumers to complete their survey (Schwarz 2007; Tormala and Rucker 2018). How can companies know which attitudes are fixed versus fleeting?

Emerging research suggests that an attitude’s longevity may stem partially from whether that attitude is based on consumers’ feelings. On the one hand, feelings can be either ephemeral in nature. They exist in the moment and then disappear. Reflecting this viewpoint, research has shown a nearly singular focus on elaborative—i.e., thoughtful—processes as particularly responsible for generating strong, long-lasting attitudes (e.g., Haugtvedt and Petty 1992). On the other hand, there is growing research that attitudes based on feelings are rather strong: they are quick to come to mind, less dependent on context, and more predictive of behavior (Lavine et al. 1998; Rocklage and Fazio 2016, 2018). This has been shown to be particularly true of positive attitudes. These findings are supported by theorizing that an emotional, feelings-based reaction provides a consumer with a strong signal of his or her attitude, thereby leading to an attitude stored more strongly in memory (Fazio 1995).

Across six longitudinal studies, we examine whether attitudes based on feelings and emotional reactions are longer-lasting. In Studies 1a and 1b, we measured consumers’ attitudes toward Christmas gifts. On the day after Christmas in 2016 and 2017, we asked participants to provide the names of three gifts they had just received. We measured the valence and emotionality of their attitudes for each gift using the Evaluative Lexicon (EL; Rocklage and Fazio 2015) both initially and again one month later. Following common practice, we calculated the stability of each attitude as the absolute difference between the valence of their attitude at each timepoint (Luttrell, Petty, and Briñol 2016).

Results are similar across both studies and thus collapsed together. Linear mixed-modeling revealed that the more a consumer’s initial attitude was based on emotion, the longer-lasting that attitude was one month after Christmas. In line with past work, this was particularly true of positive attitudes and non-significant for negative. These results held above how extremely positive or negative their initial attitude was, thereby specifying the effect of emotionality per se.

In Studies 2a-2c, we utilized a similar design, but used a large sample of 40 diverse brands that varied greatly in their normative valence as well as hedonic and utilitarian nature. Using the EL, consumers provided their attitudes toward 10 randomly-selected brands both initially and one month (Studies 2a and 2b) or two weeks later (2c). To examine emotionality’s unique effect, Studies 2b and 2c also included measures of other constructs associated with attitude strength: subjective ambivalence, certainty, and subjective knowledge (Visser, Bizer, and Krosvick 2006).

Results are similar across studies and thus collapsed together. Linear mixed-modeling revealed that the more an attitude was based on emotional reactions, the longer-lasting it was. This was again particularly true of positive attitudes, and non-significant for negative. These results held above ambivalence, certainty, knowledge, and valence extremity. We also found that although consumers can accurately predict which of their attitudes are longer-lasting, the emotionality of their attitude is unrelated to these predictions – consumers appear unaware of emotionality’s effect.
In Study 3, we examined whether the emotion conveyed in consumers’ first online review of a business predicted the change in those consumers’ evaluation in their later review of that same business. We scraped all Yelp.com restaurant reviews in Chicago, Illinois starting with the very first Yelp review in 2005 up to 2017. Yelp provides consumers the ability to review a restaurant as many times as they visit that restaurant. Thus, we measured both consumers’ initial evaluation and its emotionality as well as their evaluation when they wrote an additional review of the same restaurant. There were 75,706 reviews across 18,786 consumers. To quantify consumers’ evaluations, we calculated the absolute difference between their initial and additional review’s 1) star rating and, separately, 2) valence of the text as quantified by the EL. We followed past research and quantified reviewers’ emotionality based on their most emotional positive and negative reactions (Rocklage, Rucker, and Nordgren 2018).

Given the previous effects for positive attitudes, we first examined the extent to which reviewers expressed relatively more positive emotionality (positive minus negative emotionality). Linear mixed-modeling revealed that for both star ratings and text valence, the more positive (vs. negative) emotion consumers had initially, the less their evaluation changed across time. These results held above how extremely positive (vs. negative) their initial evaluation was. These results replicated when entering positive and negative emotionality as separate predictors in each model – positive emotionality was the only consistent predictor of greater longevity.

Across six longitudinal studies, we found that the more an attitude is based on consumers’ emotional, feelings-based reactions, the longer-lasting it is – months or even years later. Moreover, consumers appear unaware of emotionality’s effect. In sum, not all attitudes are created equal and it would benefit marketers to pay particular attention to those attitudes based more versus less on emotion.

Detrimental Trust in Automation: How Conversational Robo Advisors Leverage Trust and Mis-calibrated Risk Taking

Christian Hildebrand, University of Geneva, Switzerland

Robo advisors have been praised as the next operating system in finance and the “new wealth management interface of the 21st century” (Andrus 2014), enabling an entirely automated process of investment advisory from assessing clients’ financial goals and risk profile, to ultimately managing their portfolio.

Research on the impact of these novel forms of financial advisory has largely focused on factors related to their general acceptance, the design aspects of the interface (Kilic, Heinrich, and Schwabe 2015), and the role of cost transparency (Nussbaumer et al. 2012). Very little is known about how these interfaces may fundamentally change consumers’ experience of the advisory process and impact their perceptions of the financial services firm, as well as the downstream consequences for consumers.

The current work explores an emerging variation in modalities among robo advisors, and provides a conceptualization based on prior work on speech patterns and the formation of trust through turn-taking in human-to-human dialogue (Sprecher et al. 2013). In three experiments, we show that dialogue-based, conversational robo advisors cause greater levels of affective and cognitive trust compared to non-conversational robo advisors, resulting in a more benevolent evaluation of the financial services firm, which can lead to detrimental consequences for consumers, such as selecting objectively incorrect portfolio recommendations or accepting costly investment products.

**EXTENDED ABSTRACT**

**SESSION OVERVIEW**

Social presence signals “access to another intelligence” in technology-mediated interactions (Biocca 1997) and is sometimes described as the degree to which the other is perceived to be a real person (Gunawardena and Zittle 1997), acting with agency and “intention” (Biocca, Harms, and Burgoon 2003). The attribution of social presence has been shown to positively affect user attitudes towards telecommunication exchanges, as it implies agency and intent behind the communication (Salnäs, Rassmus-Gröhn and Sjöström 2000; Skalski and Tamborini 2007). Studies have demonstrated that feelings of social presence can motivate participant engagement (e.g., increased student participation in online courses; Picciano 2002) and improve performance on related tasks (e.g., solving a jigsaw puzzle with a remote other; Giannopoulos et al. 2008). Reversely, remote communications lacking in social presence are perceived to be impersonal, reducing information sharing with others (Leh 2001).

The four papers in this special session collectively address two central questions on technology-mediated social presence: (1) How and via which mechanism new technologies induce perceptions of social presence in both human-to-human and human-computer interaction? (2) What are the downstream consequences of technology-mediated social presence on economically relevant consumer outcomes? Hildebrand and Bergner show that conversational robo advisors can lead to miscalibrated risk-taking in financial decisions, enhancing the likelihood to accept even objectively incorrect portfolio recommendations compared to non-conversational robo advisors. In the second paper, Hess, Kelley, Scott, Schumann, and Mende explore the unintended consequences of personalized advertising, showing the detrimental effect of personalized ads on self-concept threat and enhanced feelings of embarrassment. In the third paper, Bornstein, Townsend and Irmak turn to pro-social calls for action, demonstrating that mobile technologies can lead to greater prosocial behaviour by making distant others feel close. Finally, Hosseini, Galli and Valenzuela focus on the persuasive power of perceptions of social presence in online reviews, which facilitates the imagination of a potential social interaction that elevates attitudes towards reviewers and subsequent word-of-mouth.

Together, the set of papers incorporates an expansive breadth of tech/contextual richness, ranging from robo advisors (Paper 1), in-store beacons (Paper 2), online campaigns and consumer reviews (Paper 3 and 4). Each paper also demonstrates novel mechanisms on how technology-mediated presence affects consumer decision making, including the role of affective and cognitive levels of trust (Paper 1), the role of discrete emotions (such as embarrassment) (Paper 2), how mobile technologies can induce feelings of closeness (Paper 3), or fundamental changes in attitude perceptions through facilitated visualization of the social exchange (Paper 4). All papers are in advanced stages of completion with multiple studies run.

The progressive approaches and novel results in this session are sure to induce a lively discussion and are likely to appeal not only to researchers interested in consumer-tech engagement, but to a broader audience interested in consumer-firm interactions and consumer interactions with technology more generally.
Study 1 was designed to test our hypothesis of whether conversational as opposed to non-conversational robo advisors cause greater levels of affective and cognitive trust, and whether these changes in trust trigger the predicted increase in benevolence attributions. We built a native robo advisor using the flowXO technology, mimicking the characteristics of actual conversational robo advisors across financial markets. A total of 101 active private investors (i.e., having a portfolio with a financial service provider or bank) were recruited through a European market research agency (M_age=36.57, SD_age=11.59, 36% females) and randomly assigned to either a conversational or a non-conversational advisory interface. Participants in the non-conversational condition answered a series of ten questions related to their current financial situation, goals, and perception of risk via a traditional risk assessment questionnaire (Hanna, Gutter, and Fan 2001), while those in the conversational robo advisory condition answered the same series of questions in the exact same order but provided their answers in a chat console at the bottom of the interface. Participants subsequently received a matching financial portfolio based on their current risk profile. We then assessed participants’ level of affective and cognitive trust toward the robo advisory interface (Johnson and Grayson 2005, sample item affective trust: “I felt that the system cares about listening to my financial situation to help me.”, αTrustAff=.88; sample item cognitive trust: “I truly doubt the competence of the advisory system. (reversed)”, αTrustCog=.85), and their perception of benevolent intentions of the financial services firm (Schlosser et al. 2006, sample item: “It doesn’t seem that this financial services firm would knowingly do anything to hurt me.”, αFirmBenevolence=.86). In line with our prediction, we found that consumers attributed a significantly greater level of affective trust toward the conversational robo advisory interface compared to the non-conversational interface (MConversational=4.62, MNonConversational=3.35, t(99)=4.425, p<.001), as well as a significantly greater level of cognitive trust (MConversational=4.64, MNonConversational=4.10, t(99)=2.382, p<.05). Furthermore, consumers attributed significantly greater benevolence toward the financial services firm when using the conversational as opposed to non-conversational interface (MConversational=4.27, MNonConversational=3.75, t(99)=2.384, p<.05). We observe comparatively larger effect sizes for affective compared to cognitive levels of trust (Cohen’s dTrustAff=.89, Cohen’s dTrustCog=.48) and show that both produce directionally consistent but statistically separable effects on perceptions of benevolence (95% CIParallelMediation of indirect effect [.44; 1.12]).

Studies 2 and 3 further explored the potentially detrimental consequences of more benevolent attributions on consumers’ downstream decisions. Specifically, Study 2 explores whether increased levels of cognitive and affective trust make consumers more likely to accept an objectively incorrect portfolio recommendation that is inconsistent with their actual risk profile. Replicating Study 1, we systematically altered the recommended portfolio so that risk-averse investors received more aggressive portfolio recommendations whereas risk-seeking investors received a recommended capital-preserving portfolio. All other procedures were identical to Study 1 and we used the same scale items to assess the level of affective trust (αTrustAff=.94), cognitive trust (αTrustCog=.90), and benevolence of the firm (αFirmBenevolence=.93). A total of 154 private investors (M_age=34.57, SD_age=10.62, 33.7% females) participated in this study (same pre-screening criteria as Study 1). Even though the recommended portfolio was entirely opposite to consumers’ risk profile, we observe only a moderate adjustment in cognitive trust and a marginal significant difference between both robo advisor conditions (MConversational=4.25, MNonConversational=3.84, t(152)=1.692, p=.09), while the findings on affective trust were unaffected (MConversational=4.78, MNonConversational=3.24, t(152)=5.662, p<.001). Furthermore, the findings on benevolence mirrored those on affective trust and replicated the pattern of parallel mediation revealed in Study 1. Finally, we found that while 60% of consumers in the non-conversational advisory condition adequately adjusted their recommended portfolio only 26.6% did so in the conversational robo advisor condition (χ2(1)=17.54, p<.001). This effect was robust across risk-averse and risk-seeking consumers.

Study 3 further extends these findings across a broad range of investment decisions (such as selecting among a specific percentage of active to passive investments) and shows that these effects persist even when consumers are exposed to a disclaimer highlighting the potential financial interest of the firm.

To the best of our knowledge, this is the first work that contrasts the effects of traditional, non-conversational compared to conversational, dialogue-based robo advisor interfaces. This research contributes to the emerging field of immersive consumer experiences and shows that the turn-taking interaction paradigm of conversational robo interfaces evokes more affective experiences when making financial decisions. The findings of this work have important policy and managerial implications in terms of consumer welfare and financial regulation.

### Getting Personal in Public? How Consumers Respond to Public Personalized Advertisements

#### EXTENDED ABSTRACT

Personalized advertising is well-established in settings where consumers shop in private (e.g., online). However, retailers are now expanding personalized advertising into consumers’ public life (e.g., via digital in-store displays) (Roggeveen and Sethuraman 2018). For example, state-of-the-art in-store technology allows retailers to screen visible consumer attributes (e.g., their gender, age, body-mass-index, emotional state) and to display corresponding personalized content. Little research has examined how consumers respond to such personalized advertising in public.1 Grounded in theory on impression management and self-concept, we examine how consumers respond to public personalized advertising. Three experiments assess when and why social presence and configurations of ad-self-concept congruity affect consumer responses positively or negatively.

Because personalized public ads are visible to others, social presence—i.e., the real, implied, or imagined presence of others (Latané 1981)—may alter how consumers respond to personalized ads. That is, consumers may consider public personalized ads as a self-presentation tool if these ads address certain identity appeals (e.g., Thomas et al. 2015). We suggest that consumers, when they receive a personalized ad, experience impression management concerns and have less favorable attitudes when others are present; however, this effect will be attenuated when the ad is not personalized.

To test our theorizing, Study 1 employed a 2(social presence: no, yes) × 2(personalized advertisement: no, yes) between-subjects design. One hundred seventy-six undergraduate students (84 females, M_age=20) read about a retail shopping experience in which they encounter an advertisement on a screen prominently

---

1. Notably, prior research has examined personalization techniques in online marketing (e.g., Bleier and Eisenbeiss 2015; Schumann et al. 2014). However, these studies focused on personalized ads that consumers received in private; thus, the corresponding findings may not generalize to personalized ads that target consumers in public.
displayed in the store. Social presence was manipulated by having other shoppers present or not, both in the description and images used. We manipulated personalization by describing the scanning technology as being personalized (or omitting this information). We found significant interaction effects of personalization and social presence on attitude toward the retailer ($p = .04$). To explain the significant two-way interaction, we examined effects at each level of personalization. When the ad is personalized, consumers are less favorable toward the retailer when there is social presence ($M_{\text{SocialPresence}} = 3.98$ vs. $M_{\text{NoSocialPresence}} = 4.77$; $p = .01$); this effect is attenuated when the ad is not personalized ($M_{\text{SocialPresence}} = 5.38$ vs. $M_{\text{NoSocialPresence}} = 5.21$; $F < 1$). We see the same significant pattern of effects on behavioral (purchase) intentions toward the retailer.

Next, drawing on research on self-concept congruity (Sirgy et al. 1997) and social identity threat (White and Argo 2009), we develop a fine-grained account for how the congruity between the ad and the consumers’ self-concept influences consumer response, thereby expanding prior conceptualizations of ad-self-concept congruity (e.g., Hong and Zinkhan 1995). Specifically, we examine the moderating role of whether the ad’s appeal is bolstering or threatening, as well as the moderating role of congruity between the ad and the consumer’s self-concept (high vs. low ad-self-concept congruity). Accordingly, Study 2 employed a 2 × 2 (social presence: yes, no) × 2 (ad type: bolstering, threatening) × 2 (ad-self-concept congruity: low congruity, high congruity) between-subjects design. Three hundred and eighty-seven students (140 females; $M_{\text{Age}} = 21$) participated. Participants rated the shade of their own teeth using a scale that displayed a range of different tooth shades, which enabled us to provide participants with a personalized advertisement, designed based on the condition of their own teeth, later in the study. Then, participants read a shopping scenario about encountering a personalized in-store advertisement promoting dental products. We manipulated social presence in the scenario description and images used. We find the predicted three-way interaction ($p = .04$). Results show a difference in the impact of presence of others on shoppers across different advertising appeal types and varying levels of consumers’ perceived ad-self-concept congruity on behavioral intentions. Presence of others (vs. no presence) reduces favorable intentions toward the retailer ($M_{\text{SocialPresence}} = 5.09$ vs. $M_{\text{NoSocialPresence}} = 5.52$; $p < .10$) and increases embarrassment ($M_{\text{SocialPresence}} = 4.12$ vs. $M_{\text{NoSocialPresence}} = 3.40$; $p = .03$) when the personalized advertisement is threatening and considered to have high ad-self-concept congruity. Consumers’ negative response toward the retailer in the social presence of others is mediated by increased embarrassment (95%, CI [-.2531 to -.0058]).

Study 3 replicates the mediating role of embarrassment but also reveals the mediating role of flattery. We manipulate ad-self-concept congruity and employ a 2 × 2 × 2 (social presence: yes, no) × 2 (ad type: bolstering, threatening) × 2 (ad-self-concept congruity: low congruity, high congruity) between-subjects design. Four hundred and thirty-six students (212 females; $M_{\text{Age}} = 20$) participated. Participants were randomly assigned to one of eight conditions, in which they read about a retail consumer encountering a personalized advertisement; the personalized advertisement was derived from a tooth scan, similar to Study 2. We find a difference in the impact of presence of others on shoppers across varying ad-self-concept congruity states, revealing a significant three-way interaction on attitude toward the retailer ($p = .03$). Presence of others decreases positive attitudes toward the retailer ($M_{\text{SocialPresence}} = 4.23$ vs. $M_{\text{NoSocialPresence}} = 4.57$; $p = .08$) and increases embarrassment ($p = .02$) when the personalized advertisement is threatening and considered to have ad-self-concept congruity. Moreover, the presence of others increases flattery when the personalized advertisement is bolstering and considered to have ad-self-concept congruity ($M_{\text{SocialPresence}} = 4.58$ vs. $M_{\text{NoSocialPresence}} = 4.04$; $p = .01$). Consumers’ negative response to personalized ads in the social presence of others is mediated by increased embarrassment (95%, CI [-.2410 to -.0400]). Consumers’ positive response to personalized ads is mediated by increased flattery (95%, CI [.0015 to .1207]).

Our work expands research on personalized advertising by providing evidence of how social presence impacts individuals when they are exposed to personalized content. Further, we reveal the relevance of four novel sub-types of in-/congruity (threatening ad-self-in-congruity vs. bolstering ad-self- in-congruity), which demonstrates the importance of examining the direction (i.e., valence) of ad-self-in-congruity; an insight new to consumer research.

**Distant Connection: Differences in Prosocial Behavior across Computing Devices**

**EXTENDED ABSTRACT**

Consumer charitable giving is rapidly becoming digitalized and prior research suggests that consumers tend to make higher charitable contributions when online versus offline (Network for Good 2006; Harrison-Walker and Williamson 2000). The current research aims to delve deeper into online donation behavior to determine how prosocial intention varies according to whether consumers are solicited for help while interacting with a mobile (e.g., laptop) versus stationary (e.g., desktop) computing device. Most research in consumer behavior on mobile devices focuses on the effects of touch screens (e.g., Shen, Zhang, and Krishna 2016) and screen size (e.g., Kim and Sundar 2014). However, our work operates under the assumption that these factors are held constant and emphasizes a different contrast between mobile and stationary devices: The potential for physical movement.

Mobile device users are theorized to operate in a wide-open world where the social distinction between public and private is blurred, while desktop users literally and figuratively turn their back to the world and operate in a confined social bubble (Traxler 2011). Thus, stationary and mobile device users may develop different perceptions of socially close and distant others. We propose that when compared to stationary device usage, mobile device usage will decrease (increase) the perceived psychological distance between a donor and a socially distant (close) benefactor. Social and spatial psychological distance are interrelated and perceived relative to an egocentric reference point (Maglio, Liberman, and Trope 2013). Thus, when a device enables unrestricted (restricted) spatial mobility, the egocentric reference point for social distance should shift towards distant (close) others. By reducing the psychological distance between a donor and benefactor, emotional connection increases, and prosocial behavior increases in consequence (Loewenstein and Small 2007). Yet, as connection to psychologically distal others increases, connection to psychological close others decreases in tandem (Williams and Bargh 2008). In sum, the current research hypothesizes and shows that a mobile (stationary) device user will experience more connection to and consequently be more likely to help socially distant (close) others. We examine this effect of device mobility on prosociality across three studies.

Study 1 holds device type constant and tests the effect of mobility on prosociality towards strangers. In a correlational study among laptop users, we first measure participants’ current state prosocial behavior towards strangers by asking them to answer the 10-item (a = .88) Altruistic Personality Scale (Rushton, Chrisjohn, and Fekken 1981) adapted to emphasize current state (versus trait)
using a 7-point scale (1 = “Not at all likely”, 7 = “Very likely”). We then measure how often participants move their device (1 = “Never”, 7 = “All the time”). There is a positive correlation between prosocial behaviors towards strangers and device movement ($r(214) = .22, p = .001$).

While in study 1 we held device constant and measured mobility, in study 2 we examine differences between devices (laptop versus desktop) and how ability to move these devices then influences prosocial behavior towards socially close versus distant others. Further, we find evidence for the proposed underlying process that potential for device movement increases perceived connection with far others. We also rule out alternative explanations including mode of device interaction (e.g., touching a screen), screen size, closeness to screen, visual clarity of screen, operating system, enjoyment, computer knowledge, and personal connection to device. Following the device specific questions, we measure perceived connection to both far and close others. We then measure prosociality towards strangers using the Altruistic Personality Scale from study 1. Lastly, we examine differences in choosing to help friends versus strangers versus selves through a hypothetical donation allocation plan of $100.

After controlling for all other alternative process measures, we find a positive correlation between prosocial behaviors towards strangers and device mobility (laptop = 1; desktop = 0) ($r(136) = .25, p = .003$). Moreover, we find serial mediation through device movement and connection with far others (indirect effect = .054; 95% confidence interval = [.003, .164]). There was no evidence of serial mediation through device movement and connection with close others (indirect effect = .00; 95% confidence interval = [-.003, .032]). When choosing between helping friends versus strangers, an interaction emerged in which laptop (desktop) users donated more to strangers (friends) ($M_{diff} = 6.33; SE = 2.15; F(1, 133) = 8.67, p = .004$). There was no difference between devices in allocating money to help others versus keep for oneself ($F < 1$).

Study 3 replicates the interaction in study 2 through a controlled experimental between-subjects 2 (Device: Mobile vs. Stationary) X 2 (Social Distance: Close vs. Distant) design. We randomly assign participants to either take the study on a laptop or desktop computer. Participants rated their likelihood of helping either a next-door neighbor or distant stranger whose car is broken down. An ANOVA on this prosocial behavior revealed only a main effect of the benefactor’s social distance ($F(1, 184) = 120.91, p < .001$) and an interaction of device X social distance ($F(1, 184) = 17.96, p = .009$). Among participants asked to help a socially distant benefactor, helping behavior was higher for laptop users ($M = 3.30; SD = 1.74$) than desktop users ($M = 2.64; SD = 1.55; F(1, 184) = 4.00, p = .047$). Among participants asked to help a socially close benefactor, desktop users ($M = 5.82; SD = 1.56$) were marginally more likely to help than laptop users ($M = 5.25; SD = 1.53; F(1, 184) = 3.06, p = .082$).

Together these studies reveal that using a mobile versus stationary device can alter prosocial intentions. We show that mobile (stationary) device users are more likely to help socially distant (close) others. These results offer both practical (e.g., location-based targeting for non-profit fundraising) and theoretical (e.g., mobile versus stationary device usage and perceptions of psychological distance) implications.

The Persuasive Power of Online Social Presence

EXTENDED ABSTRACT

Online reviews are an inseparable and influential part of the purchase process. They are used by 93% of US consumers to determine an enterprise quality with positive reviews encouraging consumers to engage with a business 68% of the time (BrightLocal, 2017). Thus, effective review management is paramount for market success (Mayzlin et al., 2014; Erskine, 2017; Wang et al., 2018). The research on WOM (word of mouth) has studied reviews as a form of static communication by characterizing attributes that contribute to the perceived helpfulness of reviews (e.g., Cheung & Thadani, 2012; Hong et al., 2017; King et al., 2014). In this research, we examine online reviews as a quasi-face-to-face social interaction, focusing on “social presence” as a psychological phenomenon conductive to effectiveness of online reviews (Baym, 2015). Social presence is defined as “the degree of salience of the other person in the interaction […]” (Short et al., 1976), or, more simply, as “the sense of being with another” (Biocca et al., 2003). We propose that when reading an online review, consumers feel as in the company of the reviewer and engage in an imaginary social interaction with them. As this imagined social interaction becomes more vivid, and the “sense of being with” the reviewer becomes stronger, the consumer’s attitude toward her/him becomes more favorable, which increases recommendation acceptance. Four experiments test our hypotheses:

In experiment-1, participants (156 students; 72 women; 85% 18-24 years old) had to place an order for Starbucks VIA instant coffee using a coffee-ordering application, named CooCa. The app first showed the four available flavors: Chocoloate, Caramle, Vanilla, and Spice, and then provided “CooCa’s recommended coffee of the day,” which was a randomly selected review by an unknown coffee enthusiast. Social presence was manipulated by varying the review’s narrative style (as in Zhou et al., 2004): first-person (high) vs. objective (low) narrative style. Participants then indicated the likelihood of ordering the coffee featured in the review one a seven-point likelihood scale. A seven-item and a two-item scale were used to measure social presence (Gefen & Straub, 2003) and positive attitude towards the reviewer accordingly. Consistent with our hypothesis, Social presence increased the likelihood of ordering the reviewed coffee ($\hat{b}_{Total\, Effect} = .61; \alpha_{154} = 2.17; p = .03; 95\% \, CI [.05, 1.17]$, and this effect was fully mediated by attitudes toward the reviewer ($\hat{b}_{Indirect\, Effect} = .42; \alpha_{154} = .17; 95\% \, CI [.09, .77]; \hat{b}_{Direct\, Effect} = .19; \alpha_{154} = .83; p = .40; 95\% \, CI [.26, .65]$).

Experiment-2 replicated these results in a conservative tourism context by testing the acceptance of a non-favoured travelling destination recommendation. Participants were 228 Prolific Academic users (154 women; $M_{age} = 33.5$, $SD_{age} = 12.6$), randomly assigned to either the high or the low social presence condition. Participants read three reviews of the recommended destination and indicated their willingness to take the recommendation, using a three-question seven-point Likert scale (e.g., “how likely would you choose (Tbilisi) as your travel destination?” $\alpha = .80$). Participants then completed three scales measuring social presence ($\alpha = .93$; Gefen et al., 2003; K.-M. Lee et al., 2005; Short et al., 1976); and an eight-item scale measuring attitude towards the reviewers ($\alpha = .90$). To ensure that participants received a recommendation for a non-favoured option, they first filled out a travelling preference elicitation survey where they had to rank-order four travelling styles according to their preference: “foodie,” “nature,” “culture,” and “nightlife-seeking.” The reviews featured whatever travelling style the participant had ranked in third place.
Nine participants failed to follow instructions. As before, the significant effect of social presence on willingness to travel to the recommended city ($\beta_{social\ presence} = .24$; $t(216) = 1.89$; $p = .059$; $95\% CI: -0.01, .49$) was fully mediated by attitudes toward the reviewers ($\beta_{attitude} = .09; SE = .05; 95\% CI [.002, .21]$; $\beta_{direct\ effect} = .15; \hat{\tau}(216) = 1.24$; $p = .21; 95\% CI [-.09, .38]$).

Experiment-3 investigated the proposed effect when the diagnosticity of “liking” the reviewer was not relevant and, thus, non-determinant of recommendation acceptance. People seek advice when they are uncertain about the problem they are solving (Gino et al., 2012; Gino & Moore, 2007). So, in our context, attitude towards the reviewer (mediator) should matter only when the recommended item is not favored. Participants were 206 Prolific Academic workers (132 women, $M_{age} = 35.7$, $SD_{age} = 9.9$). Two factors were manipulated between-subjects: recommender type (in-group, out-group) and recommended product (most favourite, least favourite). In addition, social presence was measured and included as a (continuous) factor in the analyses. Nineteen participants did not pass the instructional manipulation check.

Willingness to accept the book recommendation was regressed on social presence, recommended product, recommender type, and all two-way and three-way interactions. As expected, receiving the recommendation from out-group vs. in-group members reduced the chance of accepting the recommendation ($\beta = -1.81$; $t(179) = -4.55$; $p = .00$; $95\% CI [-2.59, -1.02]$). More importantly, social presence was positively associated with recommendation acceptance ($\beta = .84$; $t(179) = 3.72$; $p = .00$; $95\% CI [.39, 1.28]$). However, as hypothesized, we identified an interaction between social presence and whether the recommended product was the most or least-favored ($\beta_{Social\ Presence \times\ Recommended\ Product} = -.77$; $t(179) = -2.07$; $p = .039$; $95\% CI [-1.50, .04]$). Social presence was only significant in determining recommendation acceptance when the recommended book was non-favored: $\beta = .50$; $t(183) = 2.83$; $p = .005$. $95\% CI [.15, .74]$.

Finally, experiment-4 tests the imagery process hypothesized to underlie the effect of social presence. Forming mental images when reading verbal information involves both visual and semantic processing (Baddeley, 1992; Jiang & Wyer Jr, 2009). If the visual or the verbal components of working memory are “busy,” then the construction of vivid mental images should become impaired, or the verbal components of working memory are “busy,” then processing (Baddeley, 1992; Jiang & Wyer Jr, 2009). If the visual processing (baddeley, 1992; Jiang & Wyer Jr, 2009). If the visual processing (baddeley, 1992; Jiang & Wyer Jr, 2009). If the visual

REFERENCES

The fourth paper explains how a market responds to the disruption of a consumer practice that was previously central to the ecosystem's long-term sustainability, taking as a context the shoe repair market. It contributes to our understanding of market growth by explaining how prior destabilizing market disruptions are resolved through practice reinvention.

These four papers raise several questions, such as:
- How does market creation differ from market evolution? What unique processes explain market growth?
- How can marketers contribute to the continuous growth of their market, and in the process grab a bigger piece of the pie?

This session is envisioned as a productive inquiry of market growth that should appeal to both neophytes and experienced researchers. It will provide neophyte researchers with a broad presentation of market systems and experienced ones with insights and extensions that will add arrows to their theoretical quiver.

**The Politication of Objects: Meaning Making and Materiality in the US Cannabis Market**

**EXTENDED ABSTRACT**

Markets are political in the sense that the objects exchanged have meaning. Objects are sometimes welcomed as saviors, sometimes derided as trivial, and sometimes feared as dangerous. Previous work in consumer research has shown how media (Humphreys, 2010), consumers (Dolbec & Fischer, 2015; Scaraboto & Fischer, 2013), and companies (Giesler, 2012) play a role in legitimation of contested goods. Other work has theorized objects' roles in shaping the evolution (Martin & Schouten, 2014), relationships (Epp & Velagaleti, 2014), and practices within markets (Canniford & Shankar, 2013; Hoffman & Novak, 2017; Thomas & Epp, 2019; Thomas, Price, & Schau, 2013). Most pertinently, Martin and Schouten (2014) show how the interface between product elements and consumer uses facilitates market evolution. However, relatively little work has evaluated how object elements interface with meaning in the market and more specifically with contested or political meaning that can facilitate or impede legitimacy.

To address this gap, we examine the American recreational cannabis market, which has been legal at the state level in the states that comprise our study sample—Colorado, Washington and Oregon—for about 4 years. This market has a diverse assortment of products that expand consumption uses and meanings. From coffee pods and artisanal chocolates to lotions and smokeless vaporizing devices, the changing materiality of the tools and symbolic markers of consumption reflects active efforts on the part of producers to legitimate the category. However, full legitimacy of the market is still uncertain; recreational cannabis remains illegal at the federal level, it maintains counter-normative associations for many mainstream consumers (Robbins, 2018), and producers face strict regulations and bans on conventional advertising. It is an excellent context in which to examine the role of object elements in market legitimation.

To orient our study, we build on assemblage thinking about markets (e.g., Arsel, 2016; Weijo, Martin, & Arnould, 2018) by theorizing markets at multiple levels. We conceptualize the market as an assemblage of consumers, producers, and objects, and this assemblage is nested in a meta-assemblage, which also includes legislation, the public, and mainstream media (Caliskan & Callon, 1986;
Müller, 2015). Through this lens, we regard the recreational cannabis market as a newly-destabilized market rather than a truly new market (see Kjellberg & Olson, 2017), thus allowing us to theorize legitimation of an existing, counter-normative market.

Our theoretical attention is on the assemblages’ stability, and on their components’ capacities, which are directional and specify how a component interacts with others (DeLanda, 2006; Hoffman & Novak, 2017). Prior work has shown how material capacities, which permit or impede physical interactions between components in an assemblage, are implicated in consumer adoption of new products and market emergence (Martin & Schouten, 2014). Other work has shown how expressive capacities, which enable objects to convey particular meanings, are implicated in consumer experience (Thomas & Epp, 2019). We seek to understand how objects’ expressive capacities play a role in shaping cultural and social meanings of a market.

Our study used six types of data. First, to map legitimation at the meta-market level, we: (1) studied the changes in regulation and public opinion related to recreational cannabis; (2) conducted an automated text analysis of national, mainstream media coverage of recreational cannabis; and (3) conducted an opinion survey of approximately 500 undergraduate students in 2015, prior to the market opening, and in 2018, after the market had been open for two years. Then, to understand the dynamics at the market level, we (4) analyzed monthly sales data for all recreational products sold in Washington since the market opened. Analysis of this data enabled us to ascertain that the meta-market is restabilizing around legitimate meanings, and that object elements play a key role.

We then turned our attention to the market assemblage – producers, consumers, and products - to more deeply understand the mechanisms underlying the link between object elements and market legitimation. We (5) conducted 23 in-depth interviews with recreational cannabis consumers, including regular, irregular, and lapsed/non-users, and (6) analyzed producers through 9 in-depth interviews and 11 feature articles in the premier cannabis trade publication.

We find that expressive capacities of objects help legitimize the market through three interactions. First, mimesis involves the visual alignment of the new product with known, legitimate others. The meanings underlying the interactions between the product and other market actors become more legitimate when the products establish or strengthen visual relations with other legitimate products. Second, discursive alignment aligns the product with favorable discourses. Medical and therapeutic discourses are one key reservoir of legitimate political discourses from the adjacent medical market. Third, semantic distancing weakens unfavorable semantic relations. Expressive capacities of products enable products to shake unfavorable meanings by distancing relations with existing, illegitimate product markets.

In considering how the interactional level intersects with legitimacy at the market and meta-market level, differences between users—and their different capacities—comes to the fore. Objects have varying expressive capacities, but these do not uniformly fit with all consumers who themselves vary in capacities due to differences in experience, needs, and use. We find that expressive capacities of objects foster cultural-cognitive and normative legitimacy in different ways, including through heterogeneous objects and consumers.

Our findings offer two theoretical contributions. First, we explicate how object elements contribute legitimate meanings in a destabilized market. We develop the specific mechanisms that facilitate meaning transfer from legitimate categories to the newly-legal, focal market. This focus on legitimation rather consumer adoption responds to a call for a materially-oriented understanding of market evolution (Martin & Schouten, 2014). Second, we extend theorization on market legitimation by theorizing how meanings can stabilize a politically contested market (Caliskan & Callon, 1986; Roffe, 2016). In contrast to previous work that has focused on the importance of material capacities, we find that expressive capacities play a critical role, particularly in a politically contested market. Although all markets are in some ways political, understanding expressive capacities is especially important when examining contested markets, such as Amazon Echo smart speakers, Juul e-cigarettes, or recreational cannabis.

Collaborative Market Driving: Conceptualizing Collective Action in Market Orientation Strategies

EXTENDED ABSTRACT

Market orientation has become a generative concept in marketing research, with over 1,000 works dedicated to the topic (Jaworski and Kohli 2017). As this literature evolved, it has identified that firms can practice this orientation primarily in two ways: as market driven and market driving (Jaworski et al. 2000). As market-driven, firms seek to build competitive advantage by excelling in acquiring, disseminating, and responding to marketing intelligence about their target consumers (Day and Moorman 2010; Grewal and Tansuhaj 2001; Kohli and Jaworski 1990; Narver and Slater 1990). As market-driving, firms choose to be less guided by this information. Instead, they focus on leveraging their internal capabilities to shape market behaviors and structures in ways that improve their own competitiveness in the long run (Carpenter et al. 1997; Humphreys and Carpenter 2018; Jaworski et al. 2000; Kumar et al. 2000).

Despite this distinction, research on both types of market orientation has retained a steady focus on the self-interested action of single companies. In this view, each firm interacts with the marketplace while seeking the most effective routes to outperform its competitors. We suggest that this emphasis has occluded from the view of marketing theorists the relative importance of another major force in market evolution, namely collective action. As both conceptual and empirical research indicate, firms often lack sufficient means at the individual level to alter markets (Jaworski et al. 2000; Rao 2009). This situation often leads them to pool resources with other market actors, including those that are conventionally conceived of as their competitors (Belasco 2007; Espanzìa et al. 2014; Weber et al. 2008), and those who are avid consumers.

The present research seeks to align the emphasis of market orientation research on single firms’ strategies with the sizable evidence on the impact of collective action on market evolution. It does so through an extended case study of the rise of the US craft beer market, a phenomenon that has involved cooperation among several market actors (Carroll and Swaminathan 2000). The observation window for this context goes from 1976, when new craft breweries began to open in the country, to 2016, when popular and trade press started to recognize their growth’s slowdown. For about a decade, these firms had near-zero market share, struggling in an industry dominated by a few gigantic corporations and their aesthetically similar beers. Fast-forwarding to 2016, however, one finds a considerably altered scenario: the number of craft breweries has exploded to over 5,000, accounting for about 20% of the sales in the $100 billion US beer market and the multiplication of beer styles in the marketplace (Tuttle 2016). We studied this trajectory through interviews, participant-observation, and archival data.

Based on this study, we advance the concept of collaborative market driving, defining it as a strategy in which a set of peer firms cooperate formally and informally among themselves and with other
of complex aesthetic product is discursively constructed and communicated (Fitzmaurice 2017; Ocejo 2014) by addressing the need for explaining how such products and the markets that support them aesthetically and materially evolve.

Our findings are derived from an inductive analysis of a large qualitative dataset, composed of archival data, fieldnotes, and 14 primary and 42 secondary interviews. It concentrates on three roles within the coffee market: coffee farmers, roasters, and baristas. To analyze this dataset, we draw from Schatzki’s practice theory. In line with Humphreys and Carpenter’s (2018) depiction of markets as systems of interdependent actors across a value chain, we conceptualize a market as a constellation of practices linked through a value chain. Our process explains how a market is complexified, how complexified practices are made manageable for everyday performance, and how market actors align their practices to deliver value to the end consumer.

Market aestheticization unfolds as follows through these three mechanisms: the first process, complexification, refers to the efforts of individual actors, supported by organizations and encouraged by market initiatives, to expand the practices at the core of their everyday performances, such as farming, roasting, and brewing coffee. The result of this complexification is the aesthetic differentiation of the product of these practices, such as green beans for farming, roasted beans for roasting, and brewing coffees for baristas. Second, as complexity is inherently more difficult, it demands more resources, whether it is time, effort, or material. To make complexity manageable, practices are streamlined by market actors. Lastly, for the value of each now-complex practices to be delivered to the end of the value chain to consumers, the added value associated with each practice (e.g., farming, roasting), need to percolate down the value chain. The last mechanism, alignment, synergistically brings together actors to do so.

Market aestheticization thus operates through these three mechanisms. These mechanisms are further oriented by the end goal of actors, such as farmers, roasters, and baristas. Two overarching goals emerged from our analysis: (1) the pursuit of a ‘perfect’ end product, which we term “aesthetic perfection,” and (2) the pursuit of profitability and mass appeal, which we term “commercial success.” In contrast to existing work on creative and cultural markets (e.g., Dolbec and Fischer 2015), we show that these end goals work concomitantly, rather than through opposition, and jointly contribute to aestheticizing a market.

We provide three sets of theoretical and managerial implications. Firstly, we contribute to the literature on market systems by emphasizing how market aestheticization supports to the evolution of mature markets through time. This process deepens a market system, leading to greater product differentiation, and the development of skills and knowledge around market practices and products. Furthermore, it leads to the expansion of the market, or economic growth.

Secondly, we contribute to the literature on market system dynamics by showing how actors across the value chain can collectively propel a market through their individual pursuits, even when they have different roles, resources, understandings, ends, or goals. Our process theorization informs how markets—as diverse as those for craft beer, tattoos, or denim—have aestheticized. We show how practices complexify and deepen, and how they are streamlined to be manageable for everyday performance. These two concomitant mechanisms unfold guided by two dialectical teleologies. We thus extend existing work on the replication and adaptation of practices (Ansari, Fiss and Zajac 2010) to highlight practice evolution.
Lastly, we propose three sets of strategic implications for organizational actors in an aestheticizing market. We first offer guidelines for firms to master the complexity required to be competitive in a mature market. We second introduce a practice-based innovation approach, bringing the attention to the need for innovating on practices, rather than products, and how this can convey meaning and create value for consumers. Third, we argue that, at the market-level, organizations should collectively strive to cultivate teleologies in order to align other actors (including consumers) in a complexified market.

**Practice Ecosystems: From Consumer Practice Disruption to Market Reinvention**

**EXTENDED ABSTRACT**

Market systems shape the behavior of the consumers who live and act within them (Giesler and Fischer 2017). Consumption practices, rather than being merely individual enactments or performances, are a complex integration of “forms of bodily activities, forms of mental activities, ‘things’ and their use, a background knowledge in the form of understanding, know-how, states of emotion and motivational knowledge” (Reckwitz 2002, 249). Practice theories provide a useful conceptual lens for viewing and analyzing the ways in which micro-level phenomena, such as consumers enacting practices like paintball (Woermann and Rokka 2015) or cosplay (Seregina and Weijo 2017), shape and are shaped by macro-level structures, such as taste regimes promoted by powerful marketplace institutions (Arsel and Bean 2013).

However, by focusing analytical attention primarily on practices as they are enacted by consumers, research has not fully conceptualized the ways in which consumption practices integrate within broader market ecosystems. Such a holistic understanding is particularly important for the study of disruption in both market ecosystems and consumption practices. Consumer research has studied how new consumption practices can instigate market disruptions (Giesler 2008) and how consumers can respond to disruptions of their own practices (Phripps and Ozanne 2017). However, prior research has not examined how market ecosystems respond following the disruption of a consumer practice that was previously central to the ecosystem’s long-term sustainability.

Recent conceptual developments in practice theory have drawn attention to the material dimensions of consumption practices. Drawing on these materialist theories of practice (Schatzki 2001; Shove, Pantzar, and Watson 2012), we analyze markets as practice ecosystems consisting of human, material, and cultural resources. Studying consumption practices from an ecosystem perspective enables a clearer conceptualization of the interdependencies between multiple resources and actors integrated by a market (Storbacka and Nenonen 2011; Vargo and Lusch 2016). A practice ecosystem includes systems of consumption, as well as the systems of production, distribution, and disposal that are sometimes overlooked in consumer research.

Specifically, we examine at the ways that practice elements, including meanings, materials, and competences (Shove et al. 2012), are distributed and integrated across a practice ecosystem. This allows us to analyze and reconceptualize market disruption as a phenomenon occurring at multiple interdependent levels within a practice ecosystem, rather than as the effect of an innovative product or charismatic entrepreneur. We study practice disruption through an ethnographic and historical analysis of the U.S. footwear production, consumption, and repair ecosystem. We focus on the practice of shoe repair and its integration with the wider footwear ecosystem through interdependent meanings, materials, and competences. Our data include (1) participant observation in shoe repair shops and industry trade shows, (2) in-depth interviews with producers, retailers, distributors, repair professionals, and consumers, and (3) online and archival data mapping out past and present networks of meanings, materials, and competences shared between the shoe repair practice and the broader footwear industry.

We find that the disruption of a consumer practice can be traced to vulnerabilities across an ecosystem of production, distribution, consumption, and repair. The practice of shoe repair involves specific integrations of interdependent competences and materials. Modern industrial shoe production and distribution systems, however, decouple human competences from processes that integrate materials into meaningful, consumable forms. In this decoupled practice ecosystem, the meanings created through consumer practices of shoe wearing are relatively independent of the materials and competences integrated through shoe production, repair, and maintenance. Decoupling meanings, materials, and competences in the broader market ecosystem weakens the links these elements form between practices of shoe production, repair, and consumption—leaving the practice of shoe repair vulnerable to disruption. With few interdependencies between the practice elements involved in shoe wearing and repairing, the consumer practice of shoe repair faded from the mainstream U.S. market. This conceptualization adds cultural depth to conventional notions of disruption as a displacement of people and resources induced by the release of an innovative product or service into a market (Christensen 1997).

We also find that, following disruption, residual competences remain active within a practice ecosystem. As these competences continue to integrate both old and new materials, a disrupted practice can persist even following its mainstream market disruption. Many consumers and shoe repair professionals, for example, find ways to creatively repair shoes produced with materials and processes that appear completely divorced from those conventionally required by the practice of shoe repair.

The persistence of a disrupted practice in the market also draws attention to vulnerabilities in the new, dominant practice ecosystem. As the industrial shoe production system decoupled competences from materials, it also weakened the material links between its practices and the meaning and value experienced by consumers. We find that shoe repair practitioners exploit these weak links by creating new and revised meanings within their practice. These meanings are based on and interdependent with specific competences and materials that practitioners must integrate as they repair shoes. We find these reinvention processes occurring across a wide range of contexts—from rock climbers repurposing tools and equipment to repair their own and others’ climbing shoes, to novice cobblers bypassing traditional networks of trade-specific knowledge in order to forge meaningful ties with consumers who wear luxury dress shoes, Birkenstock sandals, or other niche market objects. Thus, by foregrounding the symbolic value of their material labor, shoe repair professionals and consumers build new identities and new markets around meanings created by the re-forging of interdependencies between the competences and materials integrated through their practices.

SESSION OVERVIEW
By virtue of the propagation of neoliberal ideology and adoption of neoliberal socio-economic policies across the globe (Foucault 2008; Harvey 2005), there has been renewed academic interest in marketization of social life—commonly understood as the infiltration of market logics into quarters of human life, such as religion, family relations, and intimacy (e.g., Hochschild 2005, 2012; Zelizer 2005). In marketing literature, consumer culture theory (CCT) scholars have yielded important insights into the marketization debate, by illuminating ways in which market logics permeate into different domains of social life and how consumers navigate these marketized domains (e.g., Epp and Velagaleti 2014; McAlexander et al. 2014; Varman, Saha and Skalen 2011; Vikas, Varman and Belk 2015; Zwick and Cayla 2011).

Sociologist Michel Callon suggests that marketization entails not only establishment of new markets in new domains i.e., extensive marketization, but also transfiguration(s) of market structures and concomitant amplification of market pressures where markets already exist i.e., intensive marketization (Callon 2016; Caliskan and Callon 2010). Borrowing this broad conceptualization, we examine some distinctive characteristics of contemporary intensive marketization(s) via empirical studies of four different cases of marketization. These studies collectively address the following questions: Through what different mechanisms does intensive marketization transpire? How does the intensification of market logics reconfigure relationships between human (and non-human) actors? What repercussions do such transformations have on consumers’ lives and how do they shape consumer subjectivities? How do consumers cope with these repercussions?

The first paper investigates the intensive marketization of dating via mobile dating apps and their gamified interfaces. Focusing on consumers’ experiences within and beyond these platforms, it characterizes the ways in which gamification as a marketizing apparatus reconfigures dating.

The second paper examines intensive marketization in the context of the American eldercare industry. It traces the emergence of this commercialized market with its attendant issues of heightened risk and greater individual/familial responsibility and demonstrates how consumers leverage resources to postpone reliance on more problematic, heavily commoditized forms of service.

The third paper examines how the emergence of digital platforms has transformed existing amateur-to-amateur markets through an amplified competition. It demonstrates that such intensive marketization is visible through easier comparisons between commodities, a transformation of users’ skills, and a modification of professional actors’ activities supporting competition between users.

The fourth paper focuses on the American firearms market, linking intensive marketization to consumer responsibilization. Motivated by dramatic shifts in the market’s socio-material elements that support the marketization of armed self-defense, it examines linkages between consumers’ response to marketization and their understandings of their constitutional right to bear firearms.

In the spirit of this year’s ACR theme of “Becoming Wise,” this session seeks to cross-fertilize established conceptualizations of marketization with novel learnings about the impact of contemporary entanglements between conflicting logics. It informs and invites discussion about theoretical debates on the intertwining of and tensions between multiple logics, formation and reconfiguration of market structures, and the concomitant restructuring of consumer subjectivities within marketized domains.

Mobile Dating Apps and the Intensive Marketization of Dating: Gamification as a Marketizing Apparatus

EXTENDED ABSTRACT

Introduction and Theoretical Background
“Dating apps are the free-market economy come to sex. The innovation of Tinder was the swipe—the flick of a finger on a picture, no more elaborate profiles necessary and no more fear of rejection; users only know whether they’ve been approved, never when they’ve been discarded... It’s telling that swiping has been familiarly incorporated into advertisements for various products, a nod to the notion that, online, the act of choosing consumer brands and sex partners has become interchangeable.” —Nancy Jo Sales, “Tinder and the Dawn of the Dating Apocalypse, Vanity Fair, August 6, 2015.

Ever since its origination amidst the boom in leisure industries at the turn of the twentieth century, the social practice of dating has been intertwined with market offerings and market-mediated meanings (Illouz 1997). From the very beginning, commercial products and services such as automobiles, movie theaters, and dance halls have been the primary settings to initiate romantic relationships. Nevertheless, due to the emergence of market-mediated matchmaking services such as computer dating, video dating, online dating websites, speed dating, and recently mobile dating apps, dating has been under the scrutiny of scholars and journalists that take an interest in the marketization of social life (e.g. Ahuvia and Adelman 1993; Heino, Ellison, and Gibbs 2010; Hirschman 1987; Illouz 1997, 2007, 2012; Weigel 2017).

As the opening quote illustrates, mobile dating apps—the latest generation of commercial introductory services that initially emerged in 2012—present a unique case of marketization. While
these platforms can be considered as successors of online dating websites, they offer a comparatively effortless, casual and fun experience. This sort of user experience is created by way of the affordances of gamification—most commonly defined as “the use of game design elements in non-game contexts” (Deterding et al. 2011: 9). Harnessing the location-based GPS capabilities of smartphones, the apps enable users to find and interact with potential dating partners within close geographical proximity (David and Cambre 2016; Lefebvre 2018). Additionally, they opt for simplified, visualized user interfaces with little information, integrating swiping, pop-up notifications and other game-like elements. Thereby, they differentiate themselves from online dating sites, the operating logic of which is based on hyper-cognized compatibility questionnaires and matching algorithms.

Focusing on consumers’ experiences within and beyond these new generation matchmaking platforms, this study examines the contemporary marketization of dating. In doing so, I draw on Callon’s comprehensive definition of marketization (Callon 2016; Caliskan and Callon 2010). According to this definition, marketization encompasses instances of extensive marketization where market logics penetrate into domains of social life which were thought to be outside the reach of these logics as well as instances of intensive marketization in which the existing market logics are reconfigured and the market’s hegemony is intensified within said domains. While the few existing consumer research studies on the marketization of dating and romance illuminate the salience of market logics within early analog introductory services and consumers’ tactics of navigating their marketized romantic lives (Ahuvia and Adelman 1993; Hirschman 1987), this study rather focuses on the reconfiguration of existing dating market logics by virtue of mobile dating apps and their gamified interfaces. I postulate that, within the context of dating, gamification operates as an apparatus of intensive marketization.

Findings

Drawing on an extensive qualitative dataset consisting of interviews with app users, branded content of major mobile dating apps, app interface walkthroughs, and archival data from traditional and digital news media, I investigate the ways in which, as an apparatus of intensive marketization, gamification reconfigures the social practice of dating.

My analysis demonstrates that by drawing the interest of an ever-growing group of emerging adults—a demographic group that has been distant to online dating websites—, the gamified app interfaces facilitate the transition from a hypercognized dating market logic—as epitomized by online dating websites—to a ludic dating market logic. The latter differs from the former as per its heuristic (versus rationalistic) choice framework, its “playing the field” (versus finding the perfect product) mode of market engagement, and its masking the romance-market entanglement under the game frame (versus an overt economistic approach). As gamification paves the way for the ascendancy of the ludic dating market logic, it reconfigures dating by trivializing romantic-sexual initiation and dissolution rituals, accentuating app users’ self-centered romantic-sexual identity projects, and permeating real life instances beyond the usage of the apps. In accordance with Callon’s definition of intensive marketization, on top of reconfiguring existing market logics, it intensifies the market’s hegemony within the domain of dating.

Contribution

In light of these findings, I strive to contribute to theoretical discussions on marketization, gamification, and romance. Firstly, while extant CCT research on marketization examined the infiltration of market logics into social domains such as religion, family relations, social hierarchies, and education and other public services (e.g. Epp and Velagaleti 2014, McAlexander et al. 2014, Varman, Saha and Skalen 2011; Patsiaouras, Saren and Fitchett 2015; Varman, Saha and Skalen 2011; Vikas, Varman, and Belk 2015), scant attention has been paid to the domain of dating and romance (c.f., Ahuvia and Adelman 1993; Hirschman 1987). I intend to extend this line of work by illuminating a case of contemporary, intensive marketization. Second, I intend to contribute to game studies literature by demonstrating that besides enhancing employee motivation, encouraging consumer engagement, and collecting consumer data (Robson et al. 2015; Seaborn and Fels 2015), gamification can also operate as an apparatus of marketization. Finally, I aim to advance the extant literature on dating and romance (e.g. Bailey 1988; Illouz 2007, 2012; Weigel 2017) by elucidating the ways in which gamification refashions dating and providing a detailed account of the emergent ludic market logic.

Marketization of Care: How Consumers Navigate the Commoditized Eldercare Services Market

EXTENDED ABSTRACT

Introduction

As Americans spend longer hours working in often precarious jobs, there has been a necessary rise in dependence on market resources for fulfillment of personal and familial needs (Hochschild 2003). This has resulted in the infiltration of market logics into intimate spheres of life which were once presumed to be outside the realm of the market. There are two prominent perspectives regarding this commercialization of intimate life: the ‘hostile worlds’ notion, which suggests that markets are spheres of utilitarianism and selfishness that promote profit-seeking, undermine collective moral values, and cause social disintegration (e.g., Polanyi 1944; Sandel 2012); a second ‘connected lives’ view emphasizes the commingling of economic activities and intimate relations (e.g., Zelizer 2005, 2011) (Epp and Velagaleti 2014; Livne 2014). Some CCT research has taken the latter approach and sought to understand how consumers manage the entwining of commercial services in family and religious lives (e.g., Epp and Velagaleti 2014; McAlexander et al. 2014; Thompson 1996).

The ascendancy of market logics and concomitant waning of the welfare logic in the eldercare industry represents intensive marketization, which signifies the escalation of market pressures and a pervasive discourse of familialism, producing additional complexity for families using marketplace services (Callon 2016; Caliskan and Callon 2010; Hooyman and Gonyea 1995). Taking cues from Callon and Zelizer, this study seeks to understand the relational work of caring in the context of dementia related eldercare. It explores how consumers negotiate this mingling of economic activities and intimate relations (e.g., Zelizer 2005, 2011) (Epp and Velagaleti 2014; Livne 2014). Some CCT research has taken the latter approach and sought to understand how consumers manage the entwining of commercial services in family and religious lives (e.g., Epp and Velagaleti 2014; McAlexander et al. 2014; Thompson 1996).

Methods

This research uses Elias’s figurational sociology (Elias 1978) and Bourdieu’s theory of capital (Bourdieu 1986) to examine the relational networks, care policies and role of capital in the eldercare market. For a sociohistorical understanding of the eldercare industry, secondary and archival resources on senior care, facility news, health policy and public health debates in print and social media
were analyzed. Subsequently, in-depth interviews were conducted with 20 primary family caregivers to understand their subjective experiences, management of available resources and tensions related to using a continuum of services (Thompson, Locander and Pollio 1989). Additionally, participant observation was conducted at caregiver support-group meetings for 12 months. Data analysis followed a hermeneutic approach (Thompson 1997).

Findings

A review of archival data and secondary literature helps trace the sociohistorical reconfiguration of the American eldercare market. Traditionally care for the elderly was performed by families. The elderly who did not possess familial or financial resources sought care in almshouses. The Social Security Act of 1935 expressing a general disapproval of these institutions that mingled the ‘worthy’ and ‘unworthy/undesirable’ needy, barred pensions for their residents. This produced the unintended consequence of founding a private nursing home industry. The passage of Medicare and Medicaid in 1965 provided additional impetus to the growth of a commercially driven and largely unregulated nursing home industry. Various subsequent acts served to regulate—and to an extent—improve the conditions in nursing homes. Since the 1980s, there has been increased emphasis on home and community-based care (Haber 2016; Haber and Gratton 1994). With the rise of neoliberalism in the 1990s, intensive marketization has further transformed the eldercare industry. Large, diversified, for-profit nursing home chains owned by private equity investors, with changing ownership and complex organizational structures have come to dominate the market, making it increasingly difficult for consumers to have clarity about ownership, costs, quality of care and redress (Harrington et al. 2017; Wilson 2007). This has contributed industry-wide to high turnover and low motivation among care workers, poor staffing ratios and care shortfalls in quality of care and quality of life (especially after facility admission), negotiate decisions with other family members and work responsibilities and navigate various dichotomies such as acknowledging patient personhood while being their decision maker. This combination of caring and economic activity by families managing care of elderly dementia patients takes place in a context of incessant negotiation, sometimes cooperative, other times full of conflict with service providers (Zelizer 2005, 165). In order to minimize these tensions, caregivers employ a variety of strategies such as monitoring, advocacy, supplementation and substitution. However, these tensions are never completely eased.

Contribution

This research contributes to work on the detrimental effects of marketization and highlights challenges such as heightened risk, vulnerability and responsibilization consumers experience (e.g., Varman and Vikas 2007; Voice Group 2010) and thus offers insights for the conference theme of ‘becoming wise’. Additionally, through the context of eldercare, it demonstrates how market reconfiguration via intensive marketization occurs and shapes consumer subjectivities. Finally, this study draws attention to the role of resources in outsourcing of care and explicates how inspired by cultural discourses, consumers employ combinations of resources and services to postpone or avoid reliance on more heavily commoditized forms of service.

Digital Platforms and the Intensive Marketization of the Second-Hand Clothing Market

EXTENDED ABSTRACT

Introduction

Since Peñaloza and Venkatesh (2006)’s call for analyzing the functioning of markets, marketing and consumer scholars have been exploring cases of new market creation (e.g., Humphreys 2010; Martin and Schouten 2014) and established market transformation (e.g., Dolbec and Fischer 2015; Ertimur and Coskuner-Balli 2015; Scaraboto and Fischer 2013). This body of literature has highlighted the active role played by a wide range of human actors in market dynamics (Giesler and Fischer 2017). Existing work has also emphasized the role played by non-humans in market (de)formation, including magazines (Martin and Schouten 2014), metrological tools (Muniesa, Millo and Callon 2007), and carts (Cochoy 2010). Recently, Perren and Kozinets (2018) shed light on an omnipresent yet overlooked non-human, digital platforms. The authors show that digital platforms shape market exchanges through their extent of consociality and intermediation. Although they bring useful insights on the functioning of peer-to-peer markets, they focus on markets that are already mediated by digital platforms. Existing amateur-to-amateur markets that have been disrupted by the emergence of digital platforms at some point in their history are out of the authors’ scope. Therefore, we aim at offering a dynamic analysis documenting how the emergence of digital platforms has transformed markets involving equivalently positioned economic actors.

To do so, we draw on the Actor-Network Theory, a framework assuming that markets are plastic entities always in the making (Callon 2010, 2017). In this perspective, the marketization process is central to the functioning of markets (Callon 2016). More precisely, intensive marketization refers to an increased and amplified competition within existing markets (Callon 2016). Armed with this conceptual apparatus, we ask the following research question: how do digital platforms contribute to the intensive marketization of amateur-to-amateur markets?

Empirical Context and Methods

To answer this question, we investigate the second-hand clothing market while focusing on the French context. French consumers have been selling and buying second-hand clothes at tag sales (“Braderie”) since the 18th century. Yet, digital platforms emerged in 2008, thus disrupting the second-hand clothing market. Instead of face-to-face interactions, buyers and sellers meet online through
digital platforms. From May 2013 to February 2019, the first author carried out a multi-method ethnography of the second-hand clothing market. She conducted 17 in-depth interviews with consumers who buy and sell second-hand clothes. She also carried out online observations of 4 digital platforms (Facebook, vestiairecollective, videdressing, and vinted), and in situ observations at offline events where amateurs meet to buy and sell second-hand clothing. The dataset includes more than 20 hours of audio recording, 120 pages of transcription, more than 200 posts from these platforms, and 35 pages of fieldnotes.

Findings
Our data shows that digital platforms have contributed to the intensive marketization of the second-hand clothing market in three ways. First, digital platforms normalize exchanged commodities. Indeed, digital platforms provide normalizing templates that users must adopt to sell their clothes: users must mention a precise set of elements (size, brand, fabric, manufacturing location), and upload three high-quality pictures (different zooms). Normalizing templates set commodities in a common calculative space, and increase competition by enhancing their visibility and facilitating comparisons. Second, digital platforms have transformed amateurs themselves by reshaping their skills. Users surpass themselves to sell and to buy efficiently. To do so, they mimic marketers’ practices (e.g., pricing strategy, relationship marketing, merchandising) while developing new, specific practices (e.g., buying a commodity to sell it right after at a higher price; selling as many commodities as possible to buy new clothes afterwards). Digital platforms force users to be faster, which means being the first seller to answer a potential buyer’s request, and being the first buyer to find a bargain. Digital platforms therefore create a competition on pace between users. Third, digital platforms have transformed the ecosystem of professional actors enabling lateral market exchanges. These professional actors have adapted their offer to support the increased competition on pace within the market. For example, virtual wallets were created to reduce payment time, and delivery services have reduced delivery lag time while increasing the number of pickup points. Those services facilitate, increase, and speed up transactions between users.

Contribution
We contribute to the literature on market dynamics by showing that the emergence of digital platforms has transformed lateral exchange markets through an increased and amplified competition between amateurs. Such intensive marketization is visible through easier comparisons between commodities, a transformation of users’ skills, and a modification of professional actors’ activities to support competition between users. Because the topic of the 2019 ACR conference is “becoming wise”, we also highlight the dark side of intensive marketization. To do so, we build on Rosa (2010) to show that intensive marketization might lead to hyperconsumption, and to the exclusion of slow users who cannot or do not want to keep the pace.

Relating Americans’ Responses to the Marketization of Armed Self-Defense to their Understandings of the Second Amendment
EXTENDED ABSTRACT

Introduction
Over the last 30 years, industry lobbying groups, conservative politicians, and American courts have expanded individual gun rights afforded by the Constitution’s Second Amendment (see District of Columbia v. Heller 2008; Melzer 2019; Waldman 2014). These expansions have shifted the responsibility of thwarting criminal activity through use of armed force from the state to individual consumers (Lott 2016; Winkler 2011), resulting in a dramatic reconfiguration of the American firearms market. The market has reoriented around different materiality; focal market offerings have shifted from long arms (i.e., rifles) to handguns (Carlson, Goss and Shapira 2019). Consumer practices, norms, and identity construction related to firearms have also shifted: fewer citizens own guns; the average number of guns per owner has increased; self-defense, rather than hunting, has become the most common reason for purchase; lawful carry of concealed handguns in public is more common (Lott 2016); and firearms are increasingly implicated in conservative identity politics (Gramlich 2018; Melzer 2019).

We conceptualize this reconfiguration as a form of intensive marketization (Caliskan and Callon 2010; Callon 2016). The firearms market has been transfigured; it has internalized socio-material elements—including court rulings, materiality, and political rhetoric—that were not previously considered part of the market (Caliskan and Callon 2010). This marketization is consistent with the capabilization step of the P-A-C-T process explicated by Giesler and Veresiu (2014), as market and political agents have responsibilized consumers to defend themselves from criminals. In our research, we ask, what are consumers’ responses to this marketization? And, how do their responses relate to their understanding of the right to bear arms granted by the U.S. Constitution?

Literature
CCT research on marketization (e.g., Giesler 2012; Luedicke, Thompson and Giesler, 2010; Martin and Schouten 2014), the responsibilization of the consumer subject (Giesler and Veresiu 2014), and consumers’ rights and responsibilities (Henry 2010) has identified the complex and dynamic relations between consumers, producers, institutions, policies, and materiality in contexts characterized by competing, contested, or emerging market logics (Callon 1986, 2016; Martin and Schouten 2014).

Giesler and Veresiu’s (2014) seminal work on responsibilization illuminated market agents’ and institutions’ efforts to construct responsible consumer subject positions but did not adequately theorize consumers’ roles in the final step, transformation, which requires consumers to accept, if not embrace, the position created. We address this gap by examining consumer responses to marketization that capabilizes them to assume the responsibility of using lethal force to stop criminal activity. Second, CCT scholarship investigating consumer rights and responsibilities has often focused on responsibilities to firms, and less directly, to family members and oneself (Henry 2010). Scholars have called for more research on consumers’ responsibilities to society (Prothero et al. 2011). We answer this call in investigating American consumers’ right to possess and use firearms.

Methods
This study is part of a multi-year, multi-sited ethnography on American gun culture. We employed social media and interview data in this study. We obtained data from a closed, moderated, five-week, Facebook group discussion focused on guns in America. The discussion occurred shortly after the highly publicized massacre at a high school in Parkland, Florida, in 2018. The Facebook data included 11,830 posts and comments from a diverse group of 150 Americans. Additionally, we conducted in-depth interviews with 15 gun-owners and non-gun-owners in Texas, a state in which handguns are common. Data were coded manually, and analyzed in iterative phases
to eventually delimit theory pertaining to our research questions (Charmaz 2006; Corbin and Strauss 1990).

Findings

We find that differences in responses to this marketization relate to consumers’ understanding of (1) the nature of the Second Amendment, across four dimensions, (2) the relationship between negative and positive freedoms implicit in the right, and (3) the roles of morality and regulation in ensuring negative freedoms.

Each dimension of understanding of the Second Amendment is a continuum, with an individual’s understanding situated somewhere between two extremes. Dimensions are: absolute—conditional, sacred—secular, necessary—extraneous, and contemporary—anti-quated. Individuals whose overall understanding leans more towards absolute, sacred, necessary, and contemporary tend toward embracing consumers’ responsibility for protecting oneself with firearms and the marketization that capabilizes them to do so. Those whose understandings lean more towards conditional, secular, extraneous, and antiquated tend toward rejecting assigning this responsibility to consumers and such marketization.

Further, we find that consumers understand the Second Amendment as a bundle of positive freedoms (Berlin 2002), including the freedoms to: defend oneself and one’s family with lethal means; be self-reliant; live a chosen lifestyle; choose from an array of firearms available in the marketplace; engage in leisure activities with firearms; and raise a militia. Consumers relate these positive freedoms to a corresponding set of negative freedoms (Berlin 2002), including, freedom from: physical harm; aggression; intimidation; and fear. Individuals who embrace responsibilization describe these positive freedoms as ensuring negative freedoms, while those who reject is describe the former as a threat to the latter.

Finally, we find that consumers who embrace the marketization deem morality and personal responsibility taught in the home as the primary means of persuading citizens to use their positive freedoms to protect one another’s negative freedoms. However, those who reject such marketization deem these means inadequate, and describe regulation as necessary to protecting negative freedoms.

Contributions

We contribute to work on marketization (Martin and Schouten 2014; Luedicke et al. 2010) by relating consumers’ understandings of their right to consume a product to their responses to intensive marketization (Callon 2016) of an activity once assigned to the state. We also contribute to work on responsibilization (Giesler and Veresiu 2014) by providing insight into the final step, transformation. Specifically, we demonstrate how consumers’ understandings of a right that is sutured to a responsible consumer subject position by consumers’ acceptance of the position.

Additionally, we extend work on consumer rights and responsibilities (Henry 2010) by introducing new concepts, negative and positive freedoms, to consumer research, and we extend scholarship on firearms (Carlson et al. 2019) by providing nuance into Americans’ understandings of the Second Amendment.

How do specific manifestations of mental health issues impact consumer behavior in ways that are often considered outside of mainstream consumer research?

Can a more comprehensive way of studying the impact of mental health issues on consumer behavior be developed?

The first presentation illustrates the relationships between stressors, mental health, and maladaptive consumption behaviors with data from a longitudinal study of servicemembers deployed to a combat zone. The second presentation shows how mental resilience is constituted by how persons experiencing and living with disabilities attempt to overcome barriers in the marketplace. The third presentation brings out hopeful strategies for consumers to improve their ‘mental wellness.’ The concluding discussion, led by an academic researcher with professional mental health experience, will weave the three projects together and address the importance of multi-method approaches to our understanding of mental health and consumption.

**Post-Traumatic Stress and Consumption Behavior**

**EXTENDED ABSTRACT**

The experience of stress and traumatic events has long been linked to negative mental and physical health outcomes. In the U.S., a large number of servicemembers and veterans continue to suffer mental health and maladaptive behavioral issues despite numerous programs that strive to mitigate negative outcomes associated with military service (Defense Health Agency 2017). The prevalence rate of mental health disorders is especially high in military populations due to key environmental exposures; for instance, direct exposure to combat has been widely associated with Post-traumatic Stress Disorder (PTSD), depression, and aggressive behaviors (Hoge et al., 2004; Hoge et al., 2007; Russell et al., 2014; 2015; Castro and McGurk, 2007).

Within the realm of consumption, adverse outcomes can involve addictive and compulsive behaviors, such as substance abuse and compulsive buying. Despite growing interest among consumer researchers on drivers of these negative behaviors, empirical evidence regarding the impact of extreme levels of stress on such outcomes is limited. It is also important to distinguish between types of stressors experienced: those related to being in a dangerous situation (e.g., a combat zone for soldiers) versus those related to being away from home.

This study investigates relationships between military deployment-related stressors and maladaptive consumer behavior outcomes. Our research draws on longitudinal survey data collected from a Guam-based National Guard unit deployed in combat to Afghanistan. Measures of exposure to combat- and deployment-related stressors were collected on location during the soldiers’ deployment. Post-deployment survey data were collected approximately 6 months after the soldiers returned to their homes, when mental and behavioral health issues often develop (Bliese et al. 2007). In addition to completing a series of clinical and mental health screening assessments such as PTSD, depression, and anxiety, respondents reported negative consumption behaviors such as alcohol (ab)use, compulsive buying, and materialism.

The sample consists of 261 soldiers with matched responses across time points (81.4% males, average age 30 years old, 78.4% native Chamorro). Initial results reveal a complex pattern for how...
experiences of combat- and deployment-related stressors relate to maladaptive consumption outcomes upon returning to Guam: deployment stressors (being away from family, not having access to the usual commodities) are related to greater levels of materialism and compulsive buying; but combat stressors (being shot at, seeing dead bodies, etc.) are related to lesser levels of compulsive buying or materialism. We also find that maladaptive substance use is indirectly related to stressors through mental health outcomes: the more PTSD, depression, or anxiety one experiences upon returning from deployment, the more likely they are to engage in risky behaviors, such as using and misusing substances (alcohol, nicotine, or other stimulants).

We discuss the role of consumption both as a direct outcome of stressful experiences and as a coping mechanism for mental health issues that emerge from these stressful experiences (Pavia and Mason 2004). We also point out the importance of distinguishing between types of stress and whether they lead to more or less maladaptive consumption outcomes and ultimately lower well-being (Burroughs and Rindfleisch 2002). This first presentation linking stressors, mental health diagnoses, and maladaptive behaviors in the marketplace, sets the stage for the next two presentations and their focus on ways to increase consumer resiliency and improve mental wellness.

Discourses of Disability: Building Physical and Mental Marketplace Resilience

EXTENDED ABSTRACT

Diversity in the marketplace and the wider society is often heralded as a positive as researchers have increasingly explored the impact, consequences, and challenges of consumption for diverse populations related to race, gender, ethnicity and nationality. Yet the challenges of consumers with disabilities are often taken for granted, under-appreciated or under-studied. Imagine a situation where you and your young son are asked by the flight attendants to disembark under-appreciated or under-studied. Imagine a situation where you and your young son are asked by the flight attendants to disembark despite the mental acumen needed for successful marketplace experiences. Thus, consumers with disabilities are an ideal context to study such resilience.

Promoting Consumer Mental Wellness Through Emotion Regulation Strategies

EXTENDED ABSTRACT

Each year, 1 in 11 adolescents and young adults have a major depressive episode in the United States (Mojtabai, Olff and Han 2016). Moreover, according to the National Institute of Mental Health, an estimated 31.9% of adolescents have had an anxiety disorder (National Comorbidity Survey 2017). Several environmental factors may help to contribute to high levels of anxiety and depression in young people (i.e., Generation Z, Millennials). However, as young people negotiate a life on social media, they may begin to evaluate themselves using excessively high standards and adopt self-perfectionism tendencies. Broadly defined, self-perfectionism involves very critical evaluations of the self. Perfectionism may also come from others and may manifest as socially prescribed perfectionism (Paik and Sanchagrin 2013; Twenge 2000). Researchers have found that young adults are reporting higher levels of socially prescribed perfectionism than previous generations (Curran and Hill 2017). This rising perfectionism is also associated with anxiety, greater physiological reactivity, and a sense of social disconnection. This research contributes to the existing literature by examining how emotion regulation strategies can help effectively manage negative emotions. Importantly, this research highlights how marketing
mechanisms, especially social marketing, can help to facilitate effective emotion regulation.

Anxiety is characterized by anticipation of future danger or misfortune, which is accompanied by a feeling of “dysphoria or somatic symptoms of tension” (American Psychiatric Association 2000, p.820). Anxiety is an unresolved fear or a state of undirected arousal. Anxiety may also be referred to as generalized anxiety, which can involve excessive worry about things such as personal health, work, social interactions, and everyday life circumstances (National Institute of Mental Health 2019). People with anxiety disorders frequently have intense, excessive and persistent worry and fear about everyday situations. Often, anxiety disorders involve repeated episodes of sudden feelings of intense anxiety, fear or terror that reach a peak within minutes (panic attacks).

Emotion regulation refers to the processes by which individuals influence which emotions they have, when they have them, how they experience them and how they express these emotions. Emotion regulation strategies may be antecedent-focused, occurring before a full emotional reaction, or response-focused, taking place after a full emotional response has been prompted (Gross 1998). Research has found that antecedent-focused strategies often accompany greater emotional well-being and are considered adaptive (Gross and John 2003).

One common antecedent-focused emotion regulation strategy is cognitive reappraisal. Cognitive reappraisal is a form of cognitive change that involves construing a potentially emotion-eliciting situation in a way that changes its emotional impact (Lazarus and Alfert 1964). For example, if repairing a home due to a flooding incident, one might view the event as an opportunity to do some decorating and give a home a facelift, as opposed to lamenting what was destroyed in the home. Because reappraisal occurs early, it can modify the entire emotional sequence before emotion response tendencies have been fully generated.

In contrast, expressive suppression is a response-focused emotion regulation strategy. It involves inhibiting the behavioral expression of an emotion (Gross 1998). For example, one might keep a poker face while holding a great hand during a card game (Gross and John 2003). Expressive suppression comes relatively late in the emotion-generative process and changes the behavioral aspect of the emotion response tendencies without reducing the experience of negative emotion. Additionally, suppression requires the individual to effortfully manage emotion response tendencies. Such efforts of suppression may lead to negative feelings about the self and alienate the individual from others, preventing the development of emotionally close relationships (Sheldon et al. 1997).

To explore this domain, a single factor (emotional regulation strategy: cognitive reappraisal, expressive control) between-subjects design was conducted using an online, non-student consumer panel (n=96). Sixty-eight percent of participants were male and 32% were female. Study participants belonged to the Millennials and Gen Z cohort, ranging in age from 22 to 35 (M= 27). Participants were told to spend at least three minutes writing about a public speaking appearance which made them anxious. The purpose of this exercise was to induce anxiety. Next, study participants viewed one of three advertisements (randomly assigned) which promoted an emotion regulation strategy—cognitive reappraisal, expressive suppression, or an advertisement non-emotional in nature. The advertisement that promoted cognitive reappraisal included the following message, “It’s okay to be nervous and anxious… Feeling nervous and doing it anyway makes us stronger.” In contrast, the message which encouraged expressive suppression featured the following verbiage: “A little nervous and anxious? Don’t let them see you sweat!” Finally, the control condition featured an advertisement for a fictitious brand of detergent. Findings indicated that individuals in the cognitive reappraisal condition (M=3.91) exhibited the most positive feelings and more effective emotion regulation than the expressive suppression (M=3.39) and control conditions (M=3.72, (F (1,92) = 3.3, p.<.05). These results can be used by institutions (e.g., schools) to develop proactive strategies to reduce anxiety and other mental health issues. Social stigmas regarding mental health can be removed and replaced by a more preemptive stance in promoting healthy coping behaviors while managing negative emotions.

Paper #4: The Effect of Anticipating Regret and Satisfaction on Hedonic vs. Utilitarian Choice
Eunice Kim, Pennsylvania State University, USA
Min Zhao, Boston College, USA

SESSION OVERVIEW
Hedonic and utilitarian choices have received significant interest in recent consumer behavior research (c.f., Alba and Williams 2013). However, most research has focused on the antecedents of hedonic and utilitarian purchases and how consumers justify hedonic purchases that tend to be more guilt-inducing (see Khan et al. 2005 for review). The current session presents four papers that push the boundaries of research in this area. Some of the questions raised in this session include, whether hedonic (vs. utilitarian) products effect shopping momentum and shopping cart abandonment differently; do hedonic (vs. utilitarian) initial purchases lead to more extreme or more tampered subsequent purchases; whether considering hedonic (vs. utilitarian) sacrifices influence donation appeals? And how anticipation of regret shifts consumer preferences between hedonic and utilitarian products depending on whether the consumption is near or far. By answering these novel questions, the current session not only sheds light on an important consumer area but also generates directions for further research on hedonic and utilitarian consumption.

The first paper by Khan et al. proposes that an initial hedonic purchase induces a justification mindset, which carries over to subsequent choices. As a consequence, the authors show that an initial hedonic purchase magnifies the compromise effect, reduces purchase momentum, and, ironically, increases the choice share of the most indulgent option in a subsequent choice set when this option is easier to justify. The second paper by Tonietto et al. examines how hedonic vs. utilitarian products fare in shopping cart abandonment decisions. They find that hedonic products are more likely to be abandoned if there is a temporal separation between when the product is added to the cart and when the final purchase decision is made. This finding generates important recommendations for online retailers of hedonic products. The third paper by Rathee et al. shows that the level of perceived sacrifice in altruistic decisions depends on whether people are led to believe they are giving up something hedonic versus utilitarian by their action. For example, individuals perceive a greater sacrifice and are more likely to donate if they are told that donating $2 is like giving up a Fruit Salad (utilitarian) versus giving up a Blueberry Muffin (hedonic)”. The last paper by Kim and Zhao examines how the temporal dimension of a decision and anticipating regret interacts to determine consumers preference for hedonic versus utilitarian options. They show that anticipating regret reduces (increases) the share of hedonic options when the choice is near (far). These findings shed a nuanced light on the role of anticipated regret in consumer choices.

Considering the relevance of hedonic and utilitarian products within the current marketplace, we expect that the session will be of interest to researchers as well as practitioners interested in self-control, sequential choices, consumer well-being, pro-social behavior and decision-making more generally. This session fits within the Becoming Wise conference theme through creating new wisdom by holistically expanding the hedonic and utilitarian choice literature.

Role of Hedonic Choices in Sequential Decision-Making

EXTENDED ABSTRACT
Everyday consumer choices involve both hedonic and utilitarian products. Hedonic products are consumed for pleasure, while utilitarian products serve functional tasks (Hirschman and Holbrook 1982). Hedonic purchases are often accompanied with guilt. Hence their choice can be enhanced if a justification is provided before consumption (see Khan et al. 2005 for review). Most prior research on hedonic consumption has however focused on how consumers decide whether or not to purchase a hedonic or utilitarian product, and less work has sought to understand downstream consequences of a hedonic or utilitarian choice. The current research bridges this gap.

Because individuals often seek to justify their decisions, and hedonic purchases are inherently more guilt-inducing and difficult to justify, we propose that a hedonic purchase triggers a justification mindset. A mindset is a cognitive schema that upon activation can persist through thought production, information retrieval, and eventually behavior, even in unrelated tasks (Gollwitzer 1990). Hence, we posit that a justification mindset triggered by a hedonic purchase will impact subsequent unrelated choices in systematic ways. We test this notion that a hedonic initial choice induces a justification mindset in six studies by exploring how an initial hedonic versus utilitarian purchase influences downstream choices.

We start by providing initial evidence that purchasing a hedonic product induces a justification mindset by examining consumers reasons for their choice. We posit that individuals in a justification mindset should give more reasons/justifications for their choices. In Study 1, online participants (N=253) were presented with either a hedonic or utilitarian backpack and decided whether or not to purchase the backpack. Subsequently, all participants listed the reasons why they did or did not purchase the backpack. As predicted, participants who decided to purchase a hedonic (vs. utilitarian) backpack listed more reasons (4.65 \text{hedonic-backpack} vs. 3.56 \text{utilitarian-backpack}, t(131.1)=3.171, p=.003), but there was no difference in the number of reasons for those who did not purchase a backpack. Thus, the guilt induced from a hedonic purchase placed individuals in a state where justifications/reasons were more readily available. Next, we examined downstream consequences to see if this justification state induced by an initial hedonic purchase persists in subsequent choices.

Advances in Consumer Research Volume 47, ©2019
Consumers often choose a middle or compromise option (Simonson 1989) as it tends to be easier to justify. We, therefore, predict that an initial hedonic purchase will subsequently increase the likelihood to choose the middle option, i.e., the compromise effect. In Study 2, participants (N=375) were first asked to imagine purchasing an expensive pair of shoes, either for a job interview (utilitarian), a party (hedonic), or no shoe manipulation (control). Then, in a supposedly unrelated task, participants chose between three cruise options that involved a price-quality trade-off. To test for the compromise effect, we computed the choice share of the middle option relative to both extreme options. There was a non-significant compromise effect in the control (38.9%\text{\_control}) and utilitarian conditions (39.7%\text{\_utilitarian}), but a significant compromise effect in the hedonic condition (50.4%\text{\_hedonic}; x^2(2)=16.439, p=.00003).

Study 3 provides evidence for a justification mindset by examining the choice for self versus others. Individuals in a justification mindset should subsequently select a utilitarian product when making a personal choice. However, hedonic options may be easier to justify for others particularly when choosing for a friend. Participants (N=428) were first asked to imagine purchasing a pair of shoes either for a job interview (utilitarian) or a party (hedonic). Next, they indicated their preference between a gift-card to The Cheesecake Factory (hedonic) and a gift-card to Walmart (utilitarian) either for themselves or to give to a friend. As expected, when the initial choice of shoes was framed as hedonic (vs. utilitarian) the share of The Cheesecake Factory was significantly lower when the participants choose the gift-card for themselves (15.1%\text{\_hedonic-shoes} vs. 27.8%\text{\_utilitarian-shoes}, x^2(1)=5.259, p=.022), but not when gift-card was chosen for a friend (24.7%\text{\_hedonic-shoes} vs. 24.6%\text{\_utilitarian-shoes}).

Study 4 examined implications of a justification mindset when the subsequent choice set contains only hedonic options. In such choice sets, an extreme indulgent option may be easier to justify than moderately indulgent options because it provides maximum goal attainment and a better reason for choice (Goldsmith and Dhar 2010). Hence, we predict that a hedonic (vs. utilitarian) initial purchase will result in greater share for the most indulgent option when all items are hedonic. Furthermore, we distinguish between tightwads and spendthrifts. Tightwads (versus spendthrifts) feel pain of pay-ment from minimal purchases and readily experience guilt (Rick et al. 2007). Thus, they may be in a justification mindset by default. Hence, we predict that spendthrifts will be more affected by an initial hedonic (vs. utilitarian) purchase. Participants (N=677) viewed either a hedonic or utilitarian backpack and were asked to imagine purchasing it. Next, participants selected between two luxury cruise options, with one option higher in price and luxurious features. Then participants completed a three-item tightwad-spendthrift scale. As predicted, spendthrifts were more likely to choose the more indulgent option after purchasing an initial hedonic item (54.8%\text{\_hedonic-backpack} vs. 35.7%\text{\_utilitarian-backpack}, p=.003), but tightwad did not show such an increase (22.9%\text{\_hedonic-backpack} vs. 29.3%\text{\_utilitarian-backpack}).

Study 5 examines the effect of a hedonic versus utilitarian initial purchase on the shopping momentum effect. Dhar et al. (2007) showed that an initial purchase can cause shopping momentum whereby increasing the likelihood of subsequent unrelated purchases. We suggest that if an initial purchase is hedonic, it will attenuate shopping momentum by inducing a justification mindset. Participants (N=117) were given an opportunity to purchase either a hedonic (fidget spinner), utilitarian (notebook), or no initial item. Subsequently, all participants were given an opportunity to purchase M&Ms. As expected, purchase of a notebook increased the purchase likelihood of M&Ms (75.0%\text{\_utilitarian} vs. 44.7%\text{\_control}), but an initial purchase of an equally priced fidget spinner did not (47.1%\text{\_hedonic} vs. 44.7%\text{\_control}; x^2(2)=8.69, p=.013).

The current research is the first to provide evidence for a justification mindset induced by an initial hedonic purchase that has consequences on downstream behavior. Prior work within hedonic-utilitarian choices primarily investigates isolated decision-making, while the current research takes a more holistic perspective through understanding how hedonic choices influence consumers’ consumption journey. **The Effect of a Temporal Separation Between Choosing and Buying on Purchase Incidence**

**EXTENDED ABSTRACT**

Consumers shopping online often leave the contents of their cart unpurchased—a behavior known as shopping cart abandonment. The present research identifies one psychological driver of abandonment. We examine situations in which consumers first make product selections and then make a final purchase decision either immediately or after an interval of time. We propose that experiencing a temporal separation when considering hedonic products produces a mismatch between consumers’ foci during choice and purchase. In particular, because hedonic products are affect-rich and tempting (O’Curry and Strahilevitz 200; Shiv and Fedorikhin 2002), at the choice stage, consumers rely on their temptations. If the purchase decision immediately follows, consumers’ purchase focus is still on temptations. However, temptations fade over time (Wang et al. 2011) and are often replaced by guilt, making it harder to justify a purchase (Kivetz and Simonson 2002; Okada 2005) and leading to cart abandonment. Conversely, choice of utilitarian purchases is generally based on reasons (Dhar and Wertenbroch 2000) – a focus unlikely to change over time.

Seven studies support a dual-process model such that hedonic (vs. utilitarian) products are uniquely prone to abandonment. Further, while maintaining affect/temptations throughout the temporal separation decreases shopping cart abandonment, focusing on reasons increases it. Finally, we provide experimental evidence for one practical way that marketers may reduce abandonment of hedonic products.

Study 1 utilized a dataset from an online retailer that included 6.8 million browsing records from 1.3 million consumers. We compared the conversion rates of two hedonic product categories (veils and gift cards) to that of three utilitarian categories (diapers, fishing poles, and laptop cords), which were confirmed by a pretest. Overall, hedonic products had lower conversion rates (veils=11.8%, gift cards=7.0%) compared to utilitarian products (diapers=15.0%, fishing poles=18.4%, laptop cords=30.67%; all ps<.001 compared to each hedonic category). Building on this, in the remaining studies, we experimentally test the role of temporal separation in situations when items have been added to one’s shopping cart.

Study 2 followed a 2(hedonic, utilitarian) x 3(temporal separation: absent, 10-minute, 2-day) design. Participants first completed a shopping task in which they imagined that they were shopping online for five different products that were all either hedonic or utilitarian. For each product category, participants were provided with an assortment of three options and selected one of the options from each of the product categories to add to their shopping cart. Then either immediately, after a ten-minute interval, or after a 2-day interval, participants returned to their cart and indicated whether they would purchase each. We found the predicted interaction. For hedonic products, experiencing a delay of 10 minutes (M=2.26 out of 5) or two days (M=2.32) decreased purchase compared to when pur-
chase immediately followed choice (M=2.98, both ps<.05). However, participants were similarly likely to purchase utilitarian products irrespective of a temporal separation (M_{utilitarian}=3.44, M_{days}=3.16, M_{absent}=3.39, all ps>.10).

Study 3 replicated the effect of a temporal separation on hedonic purchases using an incentive-compatible design. Participants were given $2, physically shopped for four 50-cent hedonic items in our lab and made purchase decisions immediately or after a 10-minute delay by actually paying the researcher. Replicating Study 2, participants who experienced a temporal separation purchased fewer hedonic items (M=1.15 out of 4) than those who did not (M=1.61, p<.05)

Studies 4a-4b next tested the role of feelings and reasons. As in Study 2, participants in Study 4a added five hedonic products to their cart and made purchase decisions immediately or after a 10-minute delay. Finally, participants indicated how focused they were on temptations (e.g., having fun) and reasons (e.g., being practical) while making their purchase decisions. Once again, participants bought significantly fewer hedonic products following a temporal separation (M_{present}=1.87 out of 5, M_{absent}=2.40, p = .014). Importantly, participants who experienced a temporal separation reported basing their purchase decisions less on feelings (M_{present}=4.43, M_{absent}=4.99, p<.01), but equally on reasons (M_{present}=5.18, M_{absent}=5.32, p>.10). Thus, temptations uniquely faded over time.

Building on this, Study 4b examined the effect of focusing on temptations versus reasons in the absence of a temporal separation in a 3-cell (temptation, reasons, control) design. As in prior studies, participants added five hedonic products to their shopping cart. Those in the control condition immediately made their purchase decisions, while those in the other conditions first responded to two questions directing their attention to either temptation (e.g., "how exciting are the items?") or reasons (e.g., "how much do you need the items?"). Focusing on reasons reduced purchase (M=1.84 out of 5) compared to the temptation (M=2.56, p<.05) and control conditions (M=2.71, p<.01), which did not differ.

Finally, Studies 5a-5b tested the efficacy of retargeting in recovering abandoned hedonic products. Study 5a followed a 3-cell (temporal separation: absent, present, retarget) design. Participants first added five hedonic products to their shopping cart. Those in the absent condition then made purchase decisions immediately while participants in the other two conditions first performed a 10-minute filler task in which they browsed a hypothetical Facebook page with videos. In the retarget condition, participants saw their previously chosen items in a banner ad on the side of the video during part of the temporal separation. Those in the separation present condition instead saw an ad unrelated to their previous choices. As predicted, those in the temporal separation condition bought fewer of the items (M=1.89 out of 5) than those in the absent (M=2.58; p = .057) and retarget conditions (M=2.52; p = .079), which did not differ. By potentially maintaining temptation during the separation, retargeting can increase purchase.

Finally, Study 5b followed a 2(hedonic, utilitarian) x 2(temporal separation, retarget) design. The same operationalization of retargeting was used as in Study 5a. Replicating Study 5a, for hedonic products, participants purchased more items if the temporal separation contained a retargeting ad (M_{Separation}=2.19, M_{Retarget}=2.92, p=.02). However, there was no such difference for utilitarian products (M_{Separation}=3.62, M_{Retarget}=3.33, p>.10).

Our results demonstrate that hedonic products are particularly likely to be abandoned, support a dual process model, and provide a meaningful intervention to help recover hedonic purchase.

### Influence of Hedonic versus Utilitarian Framing on Donation Behavior

**EXTENDED ABSTRACT**

Past research suggests that altruism is associated with making people feel good about themselves, gaining the respect of others, or perhaps even leading to a tax benefit (Andreoni 1990; Hardy and Vugt 2006; White and Peloza 2009). However, if one considers a donation as a transaction, then it essentially involves incurring costs and forfeiting benefits. Every time people engage in a virtuous act, they give up something. Therefore, altruism requires making a sacrifice for others. In this research, we focus on the sacrifice aspect of donation—when the cost of forgoing something is subjectively felt.

This research examines consumer’s willingness to donate when asked to “give up” a monetary amount that is equalized to the price of a product (similar to penny-a-day, Gourville 1998, 1999). We specifically focus on equating hedonic versus utilitarian foods in the “giving up” donation appeal. For instance, “Please Donate $2, Note, S2 is the same as giving up a Blueberry Muffin (or Fruit Salad)”.

Our main proposition is that equating a similarly priced food during a giving up appeal can change the sacrifice perception and thereby influence donation likelihood. Specifically, we propose that consumers would be more likely to donate if the donation is equated to utilitarian rather than hedonic food or even when there is no reference to food. Because utilitarian foods elicit lower positive affect than hedonic food (Shiv and Fedorikhin 1999), people feel that they are sacrificing less and hence are willing to donate more. The pinch of giving up is less with equating to utilitarian foods.

The main objective of study 1 was to investigate the influence of utilitarian food appeal when asked to donate their own money. We used a 2-cells (utilitarian vs. hedonic) between-participants design. Two tables were set up in the business school lobby. The first table had a poster about the charity, Utah Food Bank, where the research assistant helped to solicit the donations. While, the second table, few feet apart had a donation box so that participants could donate without any interference. People passing by were approached for the donation with an envelope. They saw either utilitarian appeal, “Note, S2 is the same as giving up a pack of graham crackers”, or hedonic appeal, “Note, S2 is the same as giving up a pack of chocolate chip cookies”. Results showed that reference to graham crackers significantly increased donation rates above the chocolate chip cookies condition (P_{utilitarian} = 44%, P_{hedonic} = 25%, Chi-Square = 4.02, p = .04).

We used a 2-type of appeal (giving up vs. acquisition) x 2-reference food manipulation (utilitarian vs. hedonic) between-participants design. Prior research focuses on the asymmetric impact of acquisition and forfeiture decisions. That is, a forfeiture appeal is foreseen as foregoing (cost) attributes, whereas, an acquisition appeal (e.g., S5 is how much it costs to buy 6-granola bars) is foreseen as gaining attributes (Carmon and Ariely 2000). Therefore, we expected opposite results with these two types of appeals. Results showed evidence for our proposition in the giving up appeal, a higher willingness to donate with reference to granola bars than donuts (M_{utilitarian} = 3.84, M_{hedonic} = 3.47, F(1, 90) = 14.15, p < .0001). Whereas in acquisition appeal, there was lower willingness to donate with granola bars (M_{utilitarian} = 3.58, M_{hedonic} = 4.37, F(1, 76) = 4.05, p = .04) than donuts (consistent with Savary, Goldsmith, and, Dhar 2015). Specifically, we observed that sacrifice concept was activated for giving up appeal (M_{utilitarian} = 2.51, M_{hedonic} = 3.42, F(1, 90) = 7.31, p < .01), but not for acquisition appeal (M_{utilitarian} = 3.00, M_{hedonic} = 3.02, F(1, 76) = .001, p = .94).

We used a 3-cell (hedonic vs. utilitarian vs. control) between-participants design. The objective of Study 3 was to provide ad-
ditional evidence for the sacrifice account. Sacrifice as we suggest refers to a subjective feeling of foregoing something (Powell and Van Vugt 2003). We wanted to test the potential account of cost (monetary value) perception. One could argue that sacrifice is only a component of cost, and that there is no difference between the two. The results showed that there was higher willingness to donate with Quaker Oats compared to Magnum Ice Cream bars appeal ($M_{\text{utilitarian}} = 4.97, M_{\text{hedonic}} = 4.28, F(1, 83) = 3.52, p = .06$ and control ($M_{\text{utilitarian}} = 4.97, M_{\text{control}} = 4.19, F(1, 94) = 6.35, p = .01$). Further, sacrifice perception mediated ($\beta = -.18, 95\% CI [-.384, -.017]$) our results. However, when participants completed cost valuation of donation amount, indicating how low or high was the value of $4 to them (1 = Extremely low, and 7 = Extremely high), we found no significant effect ($M_{\text{utilitarian}} = 2.66, M_{\text{hedonic}} = 2.52, M_{\text{control}} = 2.71, p > .10$).

We used a 2-food reference (utilitarian vs. hedonic) x 2-product claim (organic vs. regular) between-participants design. With the manipulation of organic claim, we tested for the change in the affect for utilitarian food, which affects sacrifice perception and thus donation rates. An organic claim leads to higher perceived tastiness of utilitarian foods than hedonic foods (Shin 2009). Participants received $1 as compensation for this study, and the dependent variable was the choice to donate or not donate this $1 upon viewing the donation appeal. A logistic regression revealed significant interaction (Wald Chi-Square = 5.23, $p = .02$) on donation rates. Specifically, in the regular claim condition, pumpkin seeds significantly increased donation rates ($P_{\text{utilitarian}} = 90\%, P_{\text{hedonic}} = 70\%, \text{Chi-Square} = 6.25, p = .01$) than the pumpkin cupcake appeal. However, in the organic claim condition, there was no difference in donation rates ($P_{\text{utilitarian}} = 74\%, P_{\text{hedonic}} = 80\%, \text{Chi-Square} = .50, p = .47$).

Despite the positive connotations of benevolence and kindness about altruism, it is also an act of sacrifice. In fact, a sacrifice made for others makes beneficence possible. In this article, we examine how individuals try to reduce sacrifice perception associated with the acts of helping.

**The Effect of Anticipating Regret and Satisfaction on Hedonic vs. Utilitarian Choice**

**EXTENDED ABSTRACT**

Researchers and marketers have focused primarily on satisfaction and regret as post-decision measures and on what leads to customer satisfaction and regret. A question that tends to be overlooked is how anticipating satisfaction and regret prior to making a decision influences consumer preferences and choices. We compare the anticipation of regret with the anticipation of satisfaction and examine how they differentially affect consumer preference for hedonic versus utilitarian options.

Prior research suggests that anticipating satisfaction increases preference for options that are easier to imagine (Dhar and Wertebroch 2000; Shiv and Huber 2000)—such as salient product options or features in a decision context (e.g., van Osselaer and Janiszewski 2012). Prior work on anticipating regret offers mixed findings. On the one hand, for near-future decisions (where a short-term goal is more salient and indulgent options are the naturally preferred default option), individuals who anticipate regret prefer options with long-term benefits (Bakker et al. 1997; Hett et al. 2000; Richard et al. 1996); however, for distant-future decisions (where a long-term goal is more salient, and options with greater long-term benefits are the default option), individuals who anticipate regret prefer indulgent options (Keinan and Kivetz 2008; Simonson 1992).

Building on these findings, we propose that anticipating satisfaction pushes consumer preferences towards the naturally preferred or default option while anticipating regret shifts consumer preferences toward the naturally less preferred option. More specifically, when the salient goal is short-term indulgence, consumers who anticipate regret prior to making their decision prefer utilitarian, virtuous options, whereas when the salient goal is long-term benefit, they prefer hedonic, indulgent options. Furthermore, as regret stems from counterfactual comparisons between the chosen option and the foregone option (Zeelenberg and Pieters 2007), we propose that while anticipating satisfaction tends to focus individuals on the positives of the chosen option, anticipating regret tends to focus individuals on the negatives of the default option and the positives of the alternate option. As a result, anticipating regret shifts preferences away from the default option.

Study 1 ($N = 114$) demonstrates the basic effect in a near future choice between two potential weekend activities: watching TV vs. going to the gym. Since individuals tend to focus on immediate benefits such as pleasure for near future decisions (Trope and Liberman 2003), watching TV would be the default option. Prior to rating the attractiveness of each option, participants anticipated how satisfied they would feel if they were to choose that activity, how much regret they would feel if they were not to choose that activity or did not anticipate anything. As a measure of considering non-salient decision aspects, they also rated the extent to which future concerns influenced their evaluations. As expected, the attractiveness of the options varied across the three conditions ($F (2, 111) = 3.99, p = .02$). Participants in the regret condition found the default TV option less attractive than the gym option compared to those in both the satisfaction and the control conditions. Similarly, thoughts of the future (i.e., long-term focus) differed across the three conditions ($F (2, 111) = 2.91, p = .06$), and it mediated the effect of anticipation type on preference.

Study 2 examined the effect in both near-future and distant-future decisions. The study was a 2 (anticipation type: satisfaction vs. regret) x 2 (time frame: tomorrow vs. three months later) between-participants design ($N = 90$). Participants imagined a dinner party that would take place tomorrow (three months later) and indicated their dessert preference between cheesecake and fruit. Prior research shows that individuals tend to focus on short-term pleasures for near future decisions and focus on long-term goals for distant future decisions (Trope and Liberman 2003). Therefore, the cheesecake (fruit) would be the default preference for the near (distant) future. Prior to deciding, participants anticipated the satisfaction (regret) with choosing (not choosing) each option in turn. As expected, we found a significant anticipation type x time frame interaction on preference ($p = .06$). When the decision was for the near future, those anticipating regret were more likely to prefer the cheesecake compared to those anticipating satisfaction ($p = .05$); however, when the decision was for the distant future, those anticipating regret were more likely to prefer the cheesecake compared to those anticipating satisfaction ($p = .05$).

Study 3 replicated the findings in a choice between steak and healthy pasta for tomorrow vs. three months later ($N = 318$). More importantly, we found that anticipating regret (vs. satisfaction) increased participants’ consideration of the negatives of the default option ($p < .01$) and the positives of the non-default option ($p < .01$), which mediated the effect of anticipation type on preference.

Next, we used goals to determine the default option in a choice set. Study 4 was a 2 (goal: studying vs. socializing) x 2 (anticipation type: satisfaction vs. regret) between-participants design ($N = 96$). After participants were primed with a goal, they were presented with a choice between going to class or having lunch with a friend. For those primed with the studying (socializing) goal, class (lunch) was the default option. Participants anticipated the satisfaction (regret)
with choosing each of the options in turn, then indicated which activity they preferred. As expected, we found a significant interaction on preference (p=.01). Among those primed with studying, those anticipating regret were more likely to prefer lunch compared to those anticipating satisfaction (p=.03); however, among those primed with socializing, those anticipating regret were less likely to prefer lunch compared to those anticipating satisfaction (p=.1).

Taken together, our findings contribute to the existing literature on self-control, satisfaction, and regret. We demonstrate that anticipating satisfaction (vs. regret) plays a critical role in self-control. When indulging is the default, anticipating regret can enhance self-control, but can worsen self-control when indulging is not the default. Our framework of regret being able to highlight the naturally ignored decision aspects also offers a potential explanation to reconcile the contradictory findings in the regret literature.

SESSION OVERVIEW

In an era of enhanced social media engagement and heightened activism, consumers are more aware than ever of company transgressions (e.g., product malfunctions, immoral behaviors, seemingly unfair promotions) and their implications for various consumer groups. This session is centered on the following questions: 1) how do consumers respond to firms that misbehave toward consumers or treat others differently (for better or for worse) and 2) what are the downstream consequences for brand perceptions and consumer loyalty? Specifically, the four papers shed light on consumers’ differential reactions to company actions that bring harm upon consumers, provide benefits to some consumers over others, and provoke consumers to sabotage the brand. The session contributes to the emerging literature on consumer responses in the age of information by highlighting research that focuses on explicit or perceived company transgressions and their effects on attitudes, word of mouth, and purchase behavior.

In the first paper, Kim et al. demonstrate that customers react differently to brand transgressions depending upon their perceptions of the brand along warmth and competence dimensions. When a brand harms others by violating societal moral standards, Kim et al. find that consumers are more likely to support brands positioned as warm (vs. competent) due to a moral decoupling process whereby observers separate judgments of character from judgments of brand performance. In the second paper, Shepherd and Light find that firms are judged more harshly when they treat specific consumer groups badly. In particular, violating vulnerable consumers’ (e.g., women, children, the elderly) rights results in greater backlash and more negative firm perceptions. In the third paper, Kähr et al. demonstrate that witnessing other consumers engage in brand sabotage in response to a brand’s transgressions increases negative firm perceptions among observers. Observers’ own self-brand connections are shown to play an important role in their responses to value-based versus performance-based brand sabotage. In the final paper, Yoon, Olson, and Duhachek provide evidence that firms can be viewed negatively by merely offering differential incentives to consumers. Although firms frequently engage in promotional activities designed to attract new customers (e.g., special discounts), these efforts can alienate existing customers by triggering feelings of betrayal.

This year’s conference theme is “Becoming Wise.” Collectively, this session expands current wisdom by applying well-established theories to understand modern marketplace realities. Due to technological advances and increased digitalization, today’s consumers have infinite access to information about companies and their latest practices. Moreover, consumers have the power to share their experiences with firms directly (positive or negative) to a wider audience and observe how other consumers are being treated by firms. In other words, consumers’ relationships with companies are becoming increasingly driven by social comparison processes among consumers (i.e., we can see what others are, and are not, getting) or higher expectations (i.e., we demand greater protection of vulnerable consumers). We expect this session to appeal to a broad audience, including researchers interested in customer-brand relationships, brand transgressions, social comparison processes, and product/service failure.

Brand Perceptions and Consumer Support in the Face of a Transgression: Warmth Over Competence

EXTENDED ABSTRACT

Brands may be seen as warm and/or competent, two dimensions which are fundamental to social perception (Fiske et al. 2002). The level of warmth signals intentions to harm another entity, and the level of competence signals the ability to act on those intentions (Fiske, Cuddy, and Glick 2007). Even though the theoretical model (i.e., the Stereotype Content Model; Fiske et al. 2002) was developed in the context of intergroup perception, additional research demonstrates that these perceptions also apply to brands (Aaker, Vohs, and Mogilner 2010; Kervyn, Fiske, and Malone 2012). Research on firm stereotypes shows that competence perceptions are more influential on consumer support (Aaker et al. 2010; Aaker, Garbinsky, and Vohs 2012). Warmth alone was not enough to improve purchase intentions; however, when competence perceptions were boosted, so was consumers’ likelihood of purchase.

Perceptions of warmth and competence may provide differing leverage for brands following a transgression (i.e., harmful and/or deceitful behavior). For example, research suggests that brand warmth leads to greater consumer-brand identification, which in turn increases brand loyalty and brand advocacy (Stokburger-Sauer, Ratneshwar, and Sen 2012). Also, given that competence signals ability, it may be difficult for consumers to justify a transgression, since a competent brand should have had the ability to prevent the mishap. Similarly, considering that warmth signals intentions, consumers may find it easier to justify a transgression by a company that they perceive to have positive intentions (e.g., by considering it a one-time incident). In order to accomplish this and continue support,
consumers may be motivated to use various tactics such as moral rationalization (i.e., the re-construal of a negative event as being less negative) or moral decoupling (i.e., separating judgments of morality from judgments of brand performance; Bhattacharjee, Berman, and Reed 2013). Therefore, we predict that following a transgression, consumers will support a warm (vs. competent) brand more (H1). We also predict that consumers will engage in more rationalizing and decoupling for a warm brand’s “bad” behavior (H2), and that these strategies will underlie the link between warmth and support (H3).

Brand perceptions may have implications for recovery efforts, which may include actions such as offering discounts to benefit consumers directly or offering donations to benefit the wider community. While both efforts are beneficial, the same action may be perceived differently depending on what brand offers it. Another factor that may affect consumer response is the fit between the brand and the remedial action. High fit between the brand and the behavior (e.g., the relatedness between a company and its corporate social responsibility efforts) predicts positive attitudes and increased purchase intentions among consumers (Becker-Olsen, Cudmore, and Hill 2006). Extending from this finding, we expect that different recovery efforts fit better with warm versus competent brands. In particular, we predict that warm (vs. competent) brands’ offers of donations are viewed more favorably, whereas competent (vs. warm) brands’ offers of discounts are viewed more favorably (H4).

Four experiments found support for our hypotheses. Study 1 manipulated warmth and competence perceptions (between-subjects) using scenarios about a neighborhood restaurant. Then, participants were presented with transgression information (i.e., “the restaurant was accused of tax evasion”). Following this, the dependent measures (i.e., likelihood of visiting the restaurant, recommending the restaurant to friends and family, and leaving a positive review for the restaurant) were presented on 7-point scales. Results revealed marginally greater support for the warm brand versus the competent brand, supporting H1 (F(1, 211) = 2.98, p = .086). In Study 2, we identified moral decoupling as a mediator of the warmth-support link and explored transgression severity as a potential moderator. We presented scenarios about a local organic coffee shop that was either known for its contribution to the community (warm) or its rapid expansion within the community (competent). We varied the severity of the transgression by stating that the beans either came from farms that use child labor (severe) or farms that produce non-organic beans (mild). There were significant main effects for both brand perception (F(1, 200) = 6.98, p = .009) and transgression severity (F(1, 200) = 22.77, p < .001) in favor of the warm (vs. competent) brand and the mild (vs. severe) transgression, respectively. Further analyses revealed that participants rationalized and decoupled more for the warm (vs. competent) brand (supporting H2), but a mediation analysis revealed that only decoupling was a significant driver of support when both reasoning strategies were included in the model (supporting H3). Study 3 replicates these mediation findings and rules out consumer-brand identification and perceived relational norms as alternative explanations. Study 4 presented participants with a warm or a competent restaurant brand that engaged in tax evasion. Following this was a statement from the brand that either included an apology, an apology with an offer of a discount to future patrons, or an apology with an offer of a donation to the local food bank (the latter two offers were financially equivalent). Consumers were more supportive of the warm brand regardless of the type of apology (main effect p = .002), but for the competent brand, support was higher when it offered a discount than when it offered a donation (p = .040), and lower than the warm brand when it offered a donation (p = .001). Consumers may think that the donation offer was a self-serving strategy on the competent brand’s part in order to win consumers back.

In sum, this research contributes to the brand perception literature by demonstrating that after a transgression, warmth perceptions lead to higher consumer support and better acceptance of remedial actions. Moreover, we show that the warmth-support link is explained by a moral decoupling process (above and beyond moral rationalization). Practically, managers may consider investing in building a friendly and welcoming brand image since it will protect the brand in times of crises.

**Putting the Harm Back into Product-Harm: Vulnerable Social Groups, Harm Perceptions, and Consumer Complaining Behavior**

**EXTENDED ABSTRACT**

Thousands of people have been hospitalized for consuming laundry detergent pods since 2012, resulting in stricter regulation, costly changes to packaging, civil lawsuits, and even calls to ban the product (Ducharme 2018; Painter 2014; Zeliger 2018). It is noteworthy that calls for changes and holding the product manufacturers responsible came from cases of young children and those with dementia consuming the product, whereas cases of teenagers and young adults intentionally biting/consuming the detergent pods on social media elicited ridicule (Ducharme 2018). Although the product and the outcomes are essentially equivalent across these scenarios, what radically differs is how consumers respond to these incidents based on the vulnerability of the person involved, and in turn perceptions of harm.

Although the product-harm crisis, consumer complaints, and service failure literatures inherently deal with instances of harm (Davidov 2003; Dawar and Lei 2009; Gelbrich and Roschk 2011; van Heerde, Helsen, and Dekimpe 2007; Whelan and Dawar 2016), there is surprisingly little account of perceived harm and its downstream consequences in these literatures. We propose that cultural norms exist around seeing certain groups as vulnerable (women, children, elderly), either based on physical sensitivity to harm or based on a diminished ability to plan and anticipate outcomes (i.e., diminished agency). Protecting the vulnerable is a moral obligation, and exploiting or failing to protect vulnerable groups can be seen as an especially egregious violation of expectations and norms, and thus subject to moral judgment (Schein and Gray 2017). We draw from the morality literature (Schein and Gray 2017) to predict that when all else is equal (e.g., description of the product failure and its outcome), if the victim of a product harm is from a vulnerable group, consumers will 1) see increased harm done, and 2) complain more or increasingly endorse various complaining behaviors (e.g., complain to the company or regulatory agency).

Study 1 analyzed over 13,000 real-world consumer complaints made to the Consumer Product Safety Commission (CPSC) and finds that women (vs. men) are over-represented in the complaints data, specifically in instances that involve someone (e.g., a husband) making a complaint on their behalf. State-level variation in complaining on behalf of women is also predicted by state-level implicit gender stereotyping scores (which are conceptually and empirically related to seeing women as vulnerable and requiring protection). Study 2 analyzes over 800,000 cases of automobile safety complaints made to the National Highway and Traffic Safety Administration’s Office of Defects. Despite men driving more and getting in more accidents (Insurance Institute for Highway Safety 2015), women are over-represented in these complaint data (as indicated by the number of
instances that the complaints make reference to “wife,” “mother,” and “daughter” as opposed to “husband,” “father,” and “son”.

Studies 3-6 feature experimental designs to show that transgressions (e.g., product failures, service encounters) against consumers belonging to groups that are perceived to be vulnerable lead to increased perceptions of harm, and in turn more complaining behavior. In Study 3, participants imagined that either their mother or father was injured by an exploding lightbulb (based off of real CPSC complaints). When the victim was one’s mother, participants saw more harm being done than when the victim was their father, even though the objective description of the outcome was the same. They also reported an increased likelihood of engaging in various complaining behaviors (e.g., complaining to the manufacturer, engaging in negative word of mouth, complaining to a consumer protection agency; Singh 1988). This effect was replicated in Study 4 in the context of a transgression involving psychological harm as opposed to physical harm (i.e., either a woman or a man was backing out of the driveway and his/her brakes failed, sending him/her backwards into the road).

Study 5 found similar effects with an elderly (vs. middle-aged) target, and in the context of financial harm resulting from perceptions of cognitive (as opposed to physical) vulnerability. Past work shows that people are motivated to perceive harm when they see an agent transgressing against a vulnerable target (Schein and Gray 2017), that people see it as a moral obligation to protect those who are vulnerable, and that moral judgments are more negative when the negative outcome is perceived to be avoidable (Alicke et al. 2008). Therefore, we predicted and found that when an elderly (vs. non-elderly) victim is transgressed against (i.e., convinced to buy insurance that she does not need), participants saw the company as failing to account for the victim’s specific vulnerability, in turn leading to increased harm perceptions, leading to increased endorsement of various complaining behaviors.

Finally, Study 6 manipulated whether or not the company should have anticipated the victim’s vulnerability. Participants read a scenario where an adult or a child accidentally consumed a sample of lemon shampoo believing it to be edible. The product was either a shampoo intended for adults, or for children. When the product was intended for children, participants 1) saw the company as more negligent in failing to account for the user’s vulnerability, and 2) increasingly endorsed various complaining behaviors when the victim was a child as opposed to an adult. However, when the shampoo was intended for adults, no differences between the adult and child victim emerged. Thus, the same vulnerability (in this case, a lack of agency/ability to foresee consequences) that makes the company more responsible can also alleviate the company of responsibility when the product is not intended for the user.

These results highlight the importance of subjective harm perceptions and the antecedents of those perceptions (i.e., whether or not the victim is perceived to be a member of a vulnerable group). Such perceptions of harm have not been fully accounted for in past work. Perceptions of harm and subsequent complaining behavior/endorsement of others’ complaining behavior can be detrimental to a company through negative word of mouth, brand reputation, boycotts, and protesting (Ward and Ostrom 2006). Importantly, the group membership of the victim is easily identifiable by a company, thus allowing them to adjust their response strategy accordingly.

How Consumer Brand Sabotage Affects Observing Consumers: Buffering versus Amplifying Effects of Consumers’ Prior Self-Brand Connections

EXTENDED ABSTRACT

Digitalization and consumer empowerment have given rise to the recent phenomenon of consumer brand sabotage (CBS), where some consumers engage in activities that deliberately try to harm a brand by impairing the brand-related associations of other consumers (Kähr et al. 2016) companies have been confronted with a new type of negative consumer behavior: consumers who have turned hostile and who are strongly determined to cause damage to the brand. Empowered by new technological possibilities, an individual consumer can now wreak havoc on a brand with relatively little effort. In reflection of this new phenomenon, the authors introduce the concept of consumer brand sabotage (CBS). Recently, the world has witnessed an increasing number of high-profile CBS activities against brands such as Gucci (e.g., attacking Gucci for a sweater many consumers perceived as racist and calling for boycott; Holcombe 2019), United Airlines (e.g., sharing a video about security personnel dragging a passenger from a United Airlines airplane; Aratani 2017), or Abercrombie & Fitch (e.g., creating and publishing a video to alter brand image by calling for distributing A&F clothing to the homeless; Karber 2013). These and similar CBS activities are often viewed by a large number of consumers and, therefore, have the potential to damage brand image, attitudes, and purchase intentions of observing consumers. For example, the “United Breaks Guitars” sabotage video on YouTube was viewed by more than 15 million people, causing an estimated damage of more than $180 million to United (The Economist 2009).

Despite the increasing frequency and severity of CBS activities, our understanding regarding the question as to how, when, and why CBS affects brand attitudes and behavioral intentions of observing consumers is very limited. What little research does exist has largely focused on the individual themselves as a brand saboteur (Kähr et al. 2016) companies have been confronted with a new type of negative consumer behavior: consumers who have turned hostile and who are strongly determined to cause damage to the brand. Empowered by new technological possibilities, an individual consumer can now wreak havoc on a brand with relatively little effort. In reflection of this new phenomenon, the authors introduce the concept of consumer brand sabotage (CBS) and not on the potentially detrimental effects among observers of the brand saboteur’s activity.

To address this gap, the current research conducted three studies. We first conducted a field survey to gain some preliminary insights and proof-of-concept regarding the damage of CBS. We managed to establish a collaboration with the market research institute GfK in Europe and contribute two unique items in a questionnaire for their annual 2017 Business Reflector survey on corporate reputation. Study 1 showed that CBS negatively affects attitudes toward the brand among third-party consumers not directly involved in the initial negative brand encounter. Thus, observing a CBS activity can significantly harm the focal brand. In addition, this study provided preliminary evidence for the fact that this effect depends on consumers’ existing strength of connection with the brand (in this case, strong levels of consumers’ brand identification buffered the negative effect).

Study 2 replicated the basic effect observed in Study 1 in a controlled setting on the online research platform Clickworker and further documented that the negative consequences of CBS differ by type of sabotage activity. Specifically, sabotage activities caused by a brand’s violation of the saboteur’s personal values (i.e., value-based
CBS) had a stronger negative effect on observing consumers’ brand attitudes and purchase intentions as compared to sabotage activities that resulted from a brand’s performance failures (i.e., performance-based CBS).

Study 3 (conducted on Amazon’s Mechanical Turk again) replicated previous effects and found that the negative effect of CBS on observing consumers depends on the strength of their prior self-brand connections (i.e., the extent to which consumers feel a sense of oneness with a brand). More specifically, in the case of value-based CBS, we observed an amplifying effect of self-brand connection. Namely, the stronger an observing consumer’s self was connected to the brand, the more intense the adverse impact of CBS was on this consumer (i.e., negative becomes even more negative). In contrast, in the case of performance-based CBS, we documented a buffering effect of self-brand connection. That is, the stronger an observing consumer’s self was connected to the brand, the weaker the adverse impact of CBS was (i.e., negative becomes less negative).

In order to better understand these contrasting effects (i.e., buffering vs. amplifying effects) of consumers’ self-brand connection, we analyzed the underlying mechanisms and identified two distinct mediators. The amplifying effect can be explained by a self-threat mechanism. Consumers who observed value-based CBS and who also were strongly connected to the brand felt that their self-concept was threatened through such a CBS activity. As a consequence, they lowered their brand evaluations (here, self-brand connection “adds fuel to the fire” such that “love becomes hate”). On the other hand, the buffering effect worked through a brand empathy mechanism. That is, highly self-brand connected consumers who were confronted with performance-based CBS were driven by their increased brand empathy to evaluate the underlying brand more benevolently (here, self-brand connection “contains the fire” to some degree because “love is blind”).

Taken together, we contribute to knowledge regarding the under-researched marketing phenomenon of CBS (Kähr et al. 2016; Nyffenegger et al. 2018) companies have been confronted with a new type of negative consumer behavior: consumers who have turned hostile and who are strongly determined to cause damage to the brand. Empowered by new technological possibilities, an individual consumer can now wreak havoc on a brand with relatively little effort. In reflection of this new phenomenon, the authors introduce the concept of consumer brand sabotage (CBS) and its consequences. Additionally, we contribute to extant research on brand transgressions and failures, which has largely focused on the transgressing brand-consumer dyad (Aaker et al. 2004; Hess et al. 2003; Tax et al. 1998). Examining how CBS affects other observing consumers uncovers a new and complementary network perspective. We further add to the extant transgression literature, which has largely focused on performance-based transgressions (Aaker et al. 2004; Einwiller et al. 2006; Puzakova et al. 2013) by comparatively examining the differential impact of value-based CBS. Finally, investigating the differential role of consumers’ prior self-brand connections in the CBS context contributes to reconciling the ongoing discussion by the two schools of thought in the service failure literature on the “love is blind” (buffering) versus “love becomes hate” (amplifying) effect of the prior consumer-company relationship (DeWitt and Brady 2003; Grégoire et al. 2009; Tax and Brown 1998). Furthermore, we shed light on the psychological mechanisms (i.e., self-threat and brand empathy) that help explain why and why these competing effects (i.e., amplifying vs. buffering) prevail. These competing effects matter as CBS is critical in enabling marketing and brand managers to effectively intervene to decrease a possible damage of CBS.

Should I Stay or Should I Go: When Our Companies Have Eyes for Other Consumers

EXCEEDED ABSTRACT

Companies invest significant resources into acquiring new customers via promotions and exclusive discounts. Sometimes, they invite existing customers to spread the word (e.g., Hello Fresh recently asked customers to “Give your friends the gift of easy home cooking with a $40 discount!”). However, these recruitment efforts may have a negative impact on existing customers. In this research, we examine how existing customers react to “their” companies offering new customers special promotions.

According to equity theory (Adams 1963), individuals compare their own ratio of “inputs” (e.g., resources like time, money, effort) to “outputs” (e.g., rewards, perks, recognition) against the ratio of others. We propose that within consumption contexts, existing customers—those who have invested in their commercial relationships—may perceive inequity when new customers receive benefits without previous resource investment. In fact, existing customers may experience feelings of betrayal, which may lead them to discontinue their relationship with the offending company and seek an alternative relationship. Not all consumers are created equal, however, as some segments may be more or less susceptible to feeling betrayed by new-customer promotions. For example, people who are naturally anxious in relationships (i.e., they fear abandonment, desire closeness) may feel greater threat when companies seek to attract new customers, whereas people who are naturally avoidant (i.e., they eschew commitment, prefer self-reliance) may feel less threat from the same behavior (Mikulincer and Shaver 2003; Sharpsteen and Kirkpatrick 1997). Drawing upon previous work highlighting the parallels between interpersonal relationships and brand relationships (Aggarwal 2004; Fournier 1998), we investigate the impact of dispositional attachment styles on switching behavior in the face of differential incentives. We test these propositions in a series of four experiments.

Experiment 1 examined existing customers’ reactions to differential incentives. Online participants (N=146) were asked to imagine that they had signed up for a new loan program from their current bank. They then saw that new customers were signing up for the same loan and receiving either a lower interest rate than themselves (other-benefit), a higher rate (self-benefit), or the same rate (control). We measured participants’ likelihood of switching companies as our key dependent variable, followed by perceived betrayal (Grégoire and Fisher 2008) as a potential mediator. As predicted, participants (existing customers) were more likely to switch when new customers received a lower interest rate (M=4.74) compared to when others received a higher interest rate (M=3.11) or the same rate (control). We measured participants’ likelihood of switching companies as our key dependent variable, followed by perceived betrayal (Grégoire and Fisher 2008) as a potential mediator. As predicted, participants (existing customers) were more likely to switch when new customers received a lower interest rate (M=4.74) compared to when others received a higher interest rate (M=3.11) or the same rate (control). We measured participants’ likelihood of switching companies as our key dependent variable, followed by perceived betrayal (Grégoire and Fisher 2008) as a potential mediator. As predicted, participants (existing customers) were more likely to switch when new customers received a lower interest rate (M=4.74) compared to when others received a higher interest rate (M=3.11) or the same rate (control). We measured participants’ likelihood of switching companies as our key dependent variable, followed by perceived betrayal (Grégoire and Fisher 2008) as a potential mediator. As predicted, participants (existing customers) were more likely to switch when new customers received a lower interest rate (M=4.74) compared to when others received a higher interest rate (M=3.11) or the same rate (control). We measured participants’ likelihood of switching companies as our key dependent variable, followed by perceived betrayal (Grégoire and Fisher 2008) as a potential mediator. As predicted, participants (existing customers) were more likely to switch when new customers received a lower interest rate (M=4.74) compared to when others received a higher interest rate (M=3.11) or the same rate (control). We measured participants’ likelihood of switching companies as our key dependent variable, followed by perceived betrayal (Grégoire and Fisher 2008) as a potential mediator. As predicted, participants (existing customers) were more likely to switch when new customers received a lower interest rate (M=4.74) compared to when others received a higher interest rate (M=3.11) or the same rate (control). We measured participants’ likelihood of switching companies as our key dependent variable, followed by perceived betrayal (Grégoire and Fisher 2008) as a potential mediator. As predicted, participants (existing customers) were more likely to switch when new customers received a lower interest rate (M=4.74) compared to when others received a higher interest rate (M=3.11) or the same rate (control). We measured participants’ likelihood of switching companies as our key dependent variable, followed by perceived betrayal (Grégoire and Fisher 2008) as a potential mediator. As predicted, participants (existing customers) were more likely to switch when new customers received a lower interest rate (M=4.74) compared to when others received a higher interest rate (M=3.11) or the same rate (control). We measured participants’ likelihood of switching companies as our key dependent variable, followed by perceived betrayal (Grégoire and Fisher 2008) as a potential mediator. As predicted, participants (existing customers) were more likely to switch when new customers received a lower interest rate (M=4.74) compared to when others received a higher interest rate (M=3.11) or the same rate (control).
start using Meal Grab’). When the promotion gave benefits to new customers versus themselves, participants were more likely to switch ($M=2.48$ vs. $M=1.60; p<.001$) and seek out an alternative relationship ($M=4.24$ vs. $M=3.76; p<.001$). Thus, inviting existing customers to control company outputs did not prevent them from looking elsewhere.

Experiments 3 and 4 examined boundary conditions. In Experiment 3, we manipulated equity directly in a 2(Other’s Input: High vs. Control) × 2(Other Benefit: Yes vs. No). Online participants ($N=205$) read a scenario about “their” airline inviting new customers to the company. High-input customers were those receiving platinum membership with another airline (“we recognize how much time and effort you’ve invested”; this information was omitted in the control condition); the benefit was being automatically rewarded with platinum membership for joining (or no mention of benefits). A main effect of Other Benefit on switching intentions ($p<.001$) was qualified by a significant interaction ($p=.022$). As predicted, high-input new customers, participants’ switching was unaffected by them receiving complimentary status or not ($p=.19$). However, when new customers had not explicitly invested in their current airline, participants were significantly more likely to switch when they would receive status ($p<.001$).

Experiment 4 introduced dispositional attachment style as a moderator. Students ($N=353$) were randomly assigned to one condition in a 2(Self Benefit: Yes vs. No) × 2(Other Benefit: Yes vs. No) between-subjects design. After completing anxiety and avoidance scales (Brennan, Clark, and Shaver 1998), participants read a scenario about a café where they were a loyal customer. One day, they visited with an acquaintance who only recently joined the loyalty program. We manipulated who received a free coffee as a part of a customer appreciation event: the acquaintance, the participant, both, or neither of them. The results revealed a marginally significant interaction on switching intentions ($p=.092$). When participants did not receive a free coffee, they were more likely to switch when new customers received a free coffee ($M=2.87$ vs. $M=2.37; p=.014$). However, when participants themselves received a free coffee, switching did not differ as a function of others’ benefits ($M_{Yes}=2.40$, $M_{No}=2.39; p>.93$). Importantly, these results were moderated by attachment style. While avoidance predicted greater switching (regardless of benefit recipient), anxiety predicted greater switching only when the acquaintance received the benefit, but the participant did not ($p<.05$).

The current research highlights the importance of retaining existing customers for company success. Four experiments suggest that companies may risk losing existing customers if they offer new-customer promotions. Existing customers may see themselves as having invested in the relationship, potentially expecting outputs commensurate with inputs. Offering incentives to new customers may spell “betrayal” to loyal customers, especially when new customers have not “earned” their benefits.

Advances in Consumer Research (Volume 47) / 157

SESSION OVERVIEW

Most consumers are averse to waste as they like to maximize the use of their purchases (Arkes 1996; Bolton and Alba 2012). Nonetheless, waste of goods is still rampant. Almost one-third of the edible food is wasted worldwide (FAO 2015). In the United States, the food waste rate is even higher at 40%, which amounts to the economic loss of $218 billion (Hoover 2017). Given its rising economic and environmental costs, understanding what leads to waste and exploring ways to reduce it is important. This session investigates antecedents and consequences of waste and proposes novel interventions to reduce waste.

Kim and Huh will begin the session by exploring a factor contributing to food waste coming from the consumer side, that is, expiration date perception. They demonstrate that a mere framing of a food item as healthy makes consumers to perceive it as expiring more quickly than when the same food is not framed as healthy. This perception then leads consumers to be more likely to waste a food item when it is framed as healthy due to a heightened concern for expiration.

Shifting the focus to the producer side, Mookerjee, Cornil and Hoegg investigate a way to reduce waste created from discarding goods not meeting beauty standards. They propose that explicitly labeling unappealing produce as “ugly” increases purchase intention from consumers because the “ugly” labeling debases beauty premium and increases the credibility of the seller. Their findings suggest that the use of “ugly” labeling can help producers avoid discarding unappealing, however edible produces.

Extending the discussion out of the food domain, Brough and Isaac examine consumers’ decision to dispose goods for symbolic reasons and further explores its consequence on consumers’ goal perception. They find that symbolic disposal decisions increase perceived goal progress because consumers perceive greater goal commitment from symbolic disposal decisions.

Finally, Rawal, Fisher and Argo end the session by proposing a new conceptualization in understanding consumer wastefulness. They advance past research by arguing how indefinitely storing usable possessions, a seemingly prudent consumer behavior, is actually wasteful. Overall, they propose to adopt a utility and marketplace centric-view instead of a monetary and individual centric-view in defining consumer wastefulness.

Together, four papers aim to expand wisdom by using well-established theories to address a new problem of waste. The first two papers focus on tackling food waste by examining antecedents of food waste whereas the last two papers examine consequences and conceptualization of general disposal behaviors. This session raises questions of what leads to waste, both at a consumer and a producer level, and how we should tackle this issue at both the practical (i.e., intervention to reduce waste) and theoretical (i.e., how to conceptualize wastefulness) level. We believe our session will attract audiences from diverse background including researchers in motivation, self-control and food, as well as those interested in public policy and ethical issues in marketing.

Expiry Date Perception and Food Disposal Decision

EXTENDED ABSTRACT

Expiration date information shapes consumers’ decisions to purchase, consume, or dispose of food (Cardello and Schultz 2003; Tiros and Heilman 2005). Despite the important role that expiration dates play in shaping consumers’ food decisions, expiration date is often absent or ambiguous and consumers need to infer it based on available cues. Apart from the apparent rotting of food, or the presence of a clearly specified expiration date, what cues can consumers rely on to judge whether food will last for a long or a short time? The current research proposes that the perceived healthiness of a food item is an important cue that consumers use to infer its expiration date.

Previous research has shown that people use what they know about the most typical member of a category to make inferences about other category members (Chin-Parker and Ross 2004). Building on this line of research, we posit that when a food’s expiration date information is absent or ambiguous, consumers will infer an expiration date based on what they know about the most typical member of the food’s category. Since fresh produce is normally considered to be the most typical member of the category of healthy food (Carels, Harper, and Konrad 2006), we propose that when the expiration date information is not available for a food belonging to the healthy food category, people infer its expiration date based on what they know about fresh produce. Because fresh produce does indeed perish quickly, we suggest that people generalize this characteristic to other healthy foods, resulting in an intuition that healthy food expires quickly.

We also demonstrate that this intuition has a significant impact on food disposal decision. Because the concern about food expiration is important for decisions to discard food (Godfray et al. 2010; Kantor et al. 1997), we posit that the intuition that healthy food expires quickly will influence consumer decisions in this context. Specifically, we propose that when consumers decide whether to eat or discard food that has been kept for a certain period of time, they will be
more likely to discard it if they perceive it as healthy food because they perceive healthy food to expire more quickly.

In Study 1, participants (N = 191) were randomly assigned to a framing condition (healthy vs. non-healthy) and viewed the same sandwich which only varied in the health score it received which was high (healthy) or low (non-healthy). All participants were asked to imagine that they had ordered the sandwich to take out and indicate the number of days they thought the sandwich would last before it went bad. As predicted, participants in the healthy condition expected the sandwich to last for a shorter period of time (M = 1.93 days, SD = 1.20) than did participants in the non-healthy condition (M = 2.39 days, SD = 1.65; p = .03).

Study 2 provides support for the proposed mechanism. If, as we argue, the intuition that healthy food expires quickly is driven by inferences drawn from knowledge about typical category members, then individuals who consider a highly perishable food to be the most typical of healthy food should hold this intuition strongly. However, individuals who consider a less highly perishable food to be the most typical of healthy food should hold this intuition less strongly. Participants (N = 505) were randomly assigned to view a breakfast bar framed as healthy or non-healthy and indicated how quickly they thought the breakfast bar would go bad. Participants were then asked to list the first food item that came to their mind when they thought of “healthy food” and indicate how easily perishable the food item they listed was. As predicted, the breakfast bar framed as healthy (M = 4.56, SD = 1.43) was perceived to expire more quickly than the bar framed as non-healthy (M = 3.85, SD = 1.66; p < .001). More importantly, the perceived perishability of the most typical healthy food listed moderated food expiration perception (p = .005). Among those who perceived the most typical healthy food to be highly perishable (at +1SD), the healthy framed bar was perceived to expire more quickly than the non-healthy framed bar (p < .001). By contrast, healthy framing did not influence the perceptions of how quickly the bar would expire among those who perceive the most typical healthy food to be not highly perishable (at -1SD; p > .1).

Study 3 examines the consequence of the intuition that healthy food expires quickly on disposal decision. Participants (N = 458) were asked to imagine that they had ordered a daily special for lunch, which was labeled either as a “daily salad special” (healthy condition) or a “daily pasta special” (control condition; Irmak, Vallen, and Robinson 2011) but same on all other aspects including the food picture and description of ingredients. Participants read that they had packed half the portion for to-go and put it in a refrigerator to eat later. They were told that they decided to clean out their refrigerator three days later and found the leftover lunch that they had put in the refrigerator. They were then asked to indicate how likely they were to discard the leftover instead of eating it for lunch and how quickly they thought their lunch would expire compared to other daily specials. As predicted, participants in the healthy condition were more likely to discard the leftover lunch (M = 4.62, SD = 2.22) than were those in the control condition (M = 4.11, SD = 2.19; p = .014). Further, the results of mediation analysis revealed that the healthy framing increases the likelihood of discarding the food through expiration date perception.

In summary, the results of three studies demonstrate that consumers have an intuition that healthy food expires more quickly than non-healthy food, and that this intuition influences the decisions to discard food. Because of the intuition, consumers are more likely to discard food when it is portrayed as healthy than non-healthy.

**Stating the Obvious: How “Ugly” Labels Can Increase Purchase of Unappealing Produce and Reduce Waste**

**EXTENDED ABSTRACT**

Consumers demand fruits and vegetables that are aesthetically pleasing, and producers and retailers meet this demand by throwing away large amounts of food that fail to meet aesthetic standards. Consequently, 20% to 40% of fresh produce is wasted, adding to the growing environmental problem of food waste (Hyslop 2015). Burgeoning research has started to investigate how marketers can prevent such waste (Grewal et al. 2019).

Recently, some retailers have proposed innovative marketing campaigns to address produce waste; for instance, French retailer Intermarché’s advertising campaign on “ugly fruits” (in French, “fruits moches”) attracted a lot of media attention. However, this campaign was primarily focused on brand building, while purchase of unappealing produce was incentivized by steep price discounts. It remains to be tested whether and why merely labeling unappealing produce “ugly” at the point of sale can increase purchase.

We contend that consumers reject unappealing produce because of the “beauty premium” effect: people display negative biases toward aesthetically unattractive individuals or products, which suffer from a wide range of negative attributions (Dion, Berscheid, and Walster 1972; Hoegg, Alba, and Dahl 2010). Applied to our context, we propose that unappealing produce are judged less tasty and less healthy, the two key attributes that motivate food consumption (Chandon and Wansink 2012). We further propose that a label that makes the aesthetic flaw explicit can help consumers overcome their biased evaluations, in line with research showing that scrutinizing the source of a biased evaluation weakens the bias (Schwarz and Clore 1983). Specifically, we suggest that explicitly labeling unappealing produce as “ugly” should increase taste and healthiness expectations, which should translate into higher purchase. This effect should occur only if the label emphasizes an obvious aesthetic flaw, rather than a less specific flaw that may have quality implications (e.g., “second-rate”, sometimes used by retailers).

While we contend that the beauty premium effect is the main obstacle to the sales of unappealing produce, and that ugly labeling increases purchase intentions through its debiasing effect, we acknowledge that other mechanisms may be at play. In particular, by emphasizing a visible flaw, ugly labeling may increase the credibility of the seller, which should increase purchase intentions (Chaiken 1980).

Study 1 was a field study at a public Farmer’s Market. We ran a stall during three consecutive Saturdays, where we sold unappealing cucumbers and carrots provided by a local supplier. We manipulated a label next to the baskets of produce: the produce was either called “ugly” (e.g., “ugly carrots”), or not (e.g., “carrots”). We changed the label on the baskets of produce “ugly” at the point of sale can increase purchase.

In Study 2, 302 MTurk participants were shown the photo of a basket of cucumbers sold at a market; we manipulated between-subject ugly labeling (“ugly cucumbers” vs. “cucumbers”) and actual appearance (unappealing vs. normal-looking). In line with our hypotheses, we found significant interaction effects of label and appearance on purchase intentions, as well as on health and taste ex-
pectations ($p' < .01$). In the absence of ugly label, participants judged unappealing (vs. normal-looking) cucumbers less tasty, less healthy, and less worthy of purchase ($p' < .01$), while in the presence of ugly label, unappealing cucumbers were judged just as tasty, healthy, and worthy of purchase as normal-looking produce ($p' > .20$). A moderated mediation model confirmed that the ugly label increased purchase intentions of unappealing cucumbers through de-biasing health and taste evaluations. Importantly, we measured the seller’s credibility, and found that it also mediated the effect of ugly labeling on purchase.

In Study 3, we tested the hypothesis that only labels that emphasize aesthetic flaws improve purchase. Five hundred MTurk participants were shown unappealing cucumbers, associated with either one of four labels. Two labels specifically pointed out that the only flaw in the produce was aesthetic (i.e., “ugly”, “misshapen”), two highlighted a flaw but did not specify what it was (i.e., “inferior”, “second-rate”). We also had a control condition with no label. We found that both “ugly” and “misshapen” increased purchase intentions, compared with the other three conditions ($p' < .01$). A mediation model confirmed the results of Study 2: the two labels focusing on aesthetics (ugly and misshapen) increased purchase intentions via their effect on taste and health perceptions, but also via their effect on seller’s credibility.

In Study 4, we further investigated the “credibility” mechanism by comparing the effectiveness of ugly labeling with a statement from what should be perceived as a credible source: an independent government body. Specifically, we used a “love food, hate waste” awareness campaign endorsed by the government. A total of 399 MTurk participants were shown a supermarket ad displaying an unappealing apple. We manipulated ugly labeling (“ugly apple” vs. “apple”), as well as the presence (vs. absence) of the “love food, hate waste” government endorsement. We found significant interactions of ugly labeling and government endorsement on purchase intentions ($p = .02$) and on seller’s credibility ($p = .03$). Both interventions equally increased purchase and credibility ($p' < .01$), but they did not have any cumulative effect. Confirming the results of the previous studies, credibility, as well as taste and health mediated the effect of ugly labeling on purchase intentions.

Our research has important managerial implications: a simple labeling technique (ugly labeling) improves purchase of unappealing produce, and is just as effective as an awareness campaign that requires more elaboration by consumers (and more effort for retailers). Theoretically, we find converging evidence of two mechanisms: ugly labeling improves a seller’s credibility, and helps overcome negative aesthetic effects by correcting biased perceptions of critical product attributes.

**Symbolic Disposal**

**EXTENDED ABSTRACT**

Marketers have long understood that consumption often occurs not only for functional, but also symbolic, purposes. Indeed, consumers engage in compensatory consumption (Rucker and Galinsky 2008) and express their identity through their purchases and possessions (Chernev, Hamilton, and Gal 2011). In contrast to the abundance of literature on symbolic consumption, very little research has examined the corollary practice of symbolic disposal. Yet we argue that like consumption decisions, many disposal decisions are symbolic.

Symbolic disposal may be defined as making disposal decisions for symbolic rather than purely functional reasons. After weight loss, for example, consumers may dispose of larger-sized clothing items not only for practical reasons (i.e., because they no longer fit) but as a symbolic ritual affirming identity change (Rubin, Shmilovitz, and Weiss 1993). Following the dissolution of a relationship, people may dispose of photos (Sas and Whittaker 2013) and other items that serve as reminders of the past relationship in order to help them move on. Sometimes consumers symbolically divest themselves of possessions in order to avoid being affiliated with an outgroup that has adopted similar products (Berger and Heath 2007).

Our specific research question in this project is whether disposal, when symbolically related to a goal (but not diagnostic of actual progress), affects perceived goal progress. We predict a symbolic disposal effect, in which disposing of an object that symbolically represents a barrier to goal pursuit can inflate one’s perception of goal progress, even when the act of disposal has no impact on actual goal progress. We attribute this effect to the notion that symbolic disposal serves as an active and emphatic signal of goal commitment.

Across three studies, we demonstrate the effect of symbolic disposal on perceived goal progress and show that this effect is mediated by increased goal commitment.

In Study 1, we compare the efficacy of acquisition versus disposal in signaling goal commitment. 79 MTurkers were asked to imagine (in a random order) having eight different goals (e.g., improve diet, improve financial stability). For each goal, participants chose which of two actions—acquisition-related vs. disposal-related—would show greater commitment. For example, the actions for the “improve diet” goal were “purchasing low-calorie snacks for your home and office” and “discarding high-calorie snacks from your home and office.” For “improve financial stability,” the actions were “opening a certificate of deposit (CD) in order to save more” or “cutting up a credit card in order to spend less.” In three of the eight scenarios, more participants selected the disposal option than the acquisition option (89%; 57%, and 52%). 42% of respondents chose the disposal option for at least half of the eight scenarios. After viewing all eight scenarios, participants were asked to determine which action, in general, shows greater commitment to a goal—acquisition or disposal. Participants chose disposal equally as often as acquisition (49% vs. 51%). Together, these results suggest that disposal can express goal commitment at least as well as acquisition in a variety of situations.

In Study 2, we show that symbolic disposal must occur in the same domain as the goal in order for disposal to affect perceptions of goal progress. When goal domain mismatches the symbolic disposal domain, the effect of disposal on goal progress perceptions is eliminated. We randomly assigned 297 MTurkers to a 2 (symbolic disposal: financial vs. fitness) x 2 (goal: financial vs. fitness) design. Participants read a vignette in which Lisa set either a financial or fitness goal, then discarded a t-shirt for reasons related to fitness (over-sized) or finances (low-quality). Goal progress was then measured: “How much progress do you think Lisa feels she has made towards achieving her [financial / fitness] goals?” (7 = Extremely strong; 1 = Extremely weak). A significant interaction effect was observed; F(1,293) = 6.60; $p = .011$. Specifically, when Lisa had a fitness goal, perceived goal progress was higher in the fitness disposal condition than in the financial disposal condition (M = 4.91 vs. M = 4.25); F(1,293) = 7.17; $p < .008$. Similarly, when Lisa had a financial goal, perceived goal progress was directionally higher in the financial disposal condition than in the fitness disposal condition, although this contrast was not significant (M = 4.52 vs. M = 4.28); p = .336. Together, the results of study 2 showed that participants perceived greater goal progress when the domains of the goal and the disposal decision matched rather than mismatched.
Finally, in Study 3, we show that when product disposal is accidental rather than volitional, the effect of disposal on goal progress perceptions is attenuated. We further show that goal commitment mediates the effect of symbolic disposal on perceived goal progress. We randomly assigned 402 MTurkers to a 2 (disposal volition: voluntary vs. accidental) x 2 (disposal relevance: goal-related vs. goal-unrelated) design. Participants read a vignette in which John had set a goal to consume less alcohol. John subsequently ordered a glass of [water / wine], which he didn’t drink [no reason offered / because it spills]. Goal progress and goal commitment were measured, and results indicated that for goal-related disposal (wine), perceived goal progress was higher when disposal was voluntary rather than accidental (M = 6.49 vs. M = 4.42). However, this difference was attenuated for goal-unrelated disposal (water).

By differentiating between disposal that occurs for functional versus symbolic reasons, this paper contributes to the literature on disposal by enhancing our understanding of consumers’ motivations for disposing of possessions. Unlike functional disposal, symbolic disposal can occur following changes in a consumer’s self-identity or severed personal or brand relationships, independent of any change in functional needs, product performance, storage space constraints, etc. We also contribute to the literature on goals and motivations by showing that both goal commitment and perceived goal progress can be influenced by symbolic disposal.

Moreover, this research contributes to the literature on waste. To reduce wastefulness, it is important to understand the antecedents of wasteful behavior. This paper suggests that one of those antecedents is a motivation to signal a symbolic message by engaging in wasteful behavior.

Rediscovering Consumer Wastefulness

EXTENDED ABSTRACT

Storing possessions is becoming an increasingly common behavior. For instance, the average American household stores about 50 items (worth $3100), which are not being used (Business Wire 2007). Moreover, the pervasiveness of storing possessions in the US created the $38 billion self-storage industry (Harris 2018). Similarly, consumers in the UK were found to own nearly 1.7 billion pounds of unused clothing (worth £30 billion), which has not been used for at least a year (Smithers 2012).

Although storing possessions may be perceived as prudent consumer behavior, it can have a negative impact on the environment and society. Specifically, we argue that when people indefinitely store goods, which can be used by others in need of those goods, they act wastefully by depriving the marketplace of the good’s utility and forcing potential users to acquire new goods, which in turn necessitates the extraction of additional resources from the environment. Stated differently, the marketplace ends up consuming resources to store goods, which can be used by others in need of those goods, they act wastefully by depriving the marketplace of the good’s utility and forcing potential users to acquire new goods, which in turn necessitates the extraction of additional resources from the environment.

Storing possessions is an increasingly common behavior. Although these definitions identify instances of wasteful behaviors, the conceptualization is limited in several important ways. First and foremost, these definitions consider goods as either being used or discarded without the potential for them to be stored, which, as we argue, is becoming an increasingly widespread behavior. Narrowing consumer behavior to either acquiring or discarding products, prompts wastefulness to be treated as a utilization problem, such that consumers can be less wasteful by either decreasing over-utilization or increasing under-utilization or non-utilization of products. We advance this notion by suggesting that wastefulness be treated as an allocation problem in which resources need to be distributed to potential users for the system to be less wasteful instead of being stored indefinitely with non-users.

Second, previous conceptualizations of wastefulness have primarily emphasized monetary waste as a means of evaluating wastefulness. Arkes (1996; study 1) found that people identify “waste or loss of money” as the most common form of consumer wastefulness. Moreover, evaluation of others’ wastefulness has also been based on inappropriate use of money (Kirmani 1990; Townsend 2017). The broad emphasis on monetary wastefulness originates in the traditional tenet of cost-benefit reasoning, which suggests that the cost (i.e. money) expended in acquiring goods needs to be recovered to be less wasteful (Csiszentmihalyi 2000). However, we propose evaluating wasteful behaviors with an emphasis on stored utility that is wasted by not being available to users in the marketplace. Utility is derived from natural resources, which form a part of the limited public good, and therefore needs to be conserved.

Finally, past research assesses consumer wastefulness at the level of individual consumers. Although this puts the onus on individual consumers to be less wasteful (Wall 2000), it also motivates consumers to estimate wastefulness for themselves, without considering the impact of their behaviors on the ecosystem. We propose to assess wastefulness at the level of the marketplace. The individual-centric view suggests that cost of the product needs to be recovered from its utility in order to not be wasteful, whereas a marketplace-centric view suggests that resources, which have been consumed in manufacturing finished products, need to be allocated to potential users in order to not be wasteful. Thus, storing possessions may be perceived as non-wasteful (or even prudent) to the owner, but it is wasteful for the marketplace because it compels potential users to acquire new goods and consume additional resources while existing goods remain unconsumed. So instead of indefinitely storing posses-
sions, owners can be less wasteful by selling their possessions in the secondary market, donating it to charities or giving it away to friends and family who are likely to use those products.

In sum, we advance the extant literature on wastefulness by identifying the common practice of indefinitely storing possessions as an important source of consumer wastefulness in the marketplace. Thus, consumers need to be made aware of this wastefulness and, as stewards of their possessions, they should dispose of leftover utility in these possessions to potential users in the secondary markets.

SESSION OVERVIEW
Mental accounting (Thaler 1985) explains investment decisions (Benartzi and Thaler 1995; Odean 1998), choices of payment (Prelec and Loewenstein 1998), commodity purchases (Hasting and Shapiro 2013), and product replacement decisions (Okada 2001), far better than conventional theories. This session explores uncharted, but important, applications and implications of consumer mental accounting theory across several domains: dynamic risk-taking, earmarking, contingent promotions, and interpersonal sunk-costs. The papers in this session offer novel insights into how mental accounting operates in these various domains, and how it shapes consumer decisions.

The first paper (Kim, Imas, and Olivola) develops and tests a model based on mental accounting and cumulative prospect theory, to explain risk-taking over time. Consistent with the model, people take on progressively more risk after prior losses when they are faced with positively-skewed risks (i.e., low probabilities of large gains and high probabilities of small losses) and when they know the total number of investment opportunities. Also consistent with the model, framing risky investments as the default and losses as non-gains increases overall risk-taking.

The second paper (Pomerance, Reinholtz, Spiller, and Webb) examines the influence of earmarking on spending decisions. It shows that earmarking reduces spending in non-earmarked domains, and makes consumers more inelastic to a price surge in the earmarked consumption. These effects occur because earmarking separates psychological spending and economic spending. As a result, consumers behave as if they have already made the payment once their money is earmarked.

The third paper (Cheng and Gonzales) demonstrates that contingent promotions lower reference prices and can, as a result, decrease transaction utility when those promotions are unattainable. For example, given a choice between a store with a weekday-discount and another store without that discount, weekend-customers prefer the latter, because visiting the former feels more painful due to the salient unattainable promotion opportunity. Similarly, when a channel offers a contingent, yet unredeemable promotion, some consumers opt for a competing channel that sells the same product at a higher price. The transaction disutility created by salient, yet unattainable, contingent promotions drives these normatively irrational decisions.

Finally, the fourth paper (Olivola, Kim, and Hart) shifts the scope toward consumer decision-making involving other people, by examining moderators and extensions of the interpersonal sunk-cost effect: when consumers pursue an inferior option because others have invested non-recoverable resources to obtain it. This paper shows that consumers are less likely to honor interpersonal sunk-costs once the investor is no longer present. By contrast, the amount of social reciprocity (i.e., number of investors) does not moderate the interpersonal sunk-cost effect. Moreover, this paper reveals that investors themselves also exhibit a type of interpersonal sunk-cost effect.

Together, the four papers in this session document, and explain, novel consumer decision-making “anomalies” that fit within the theory of mental accounting. These papers also extend mental accounting, by highlighting novel aspects and implications of this theory. In sum, this session showcases how we can use mental accounting to identify and correct suboptimal consumption and purchasing decisions, and hence help consumers ‘become wiser.’

EXTENDED ABSTRACT
Prior losses significantly affect risk-taking. People are generally risk-averse, but take on progressively more risk in an attempt to recoup prior losses (i.e., loss-chasing)—a tendency that can significantly impact financial well-being. For example, a once successful derivatives trader at Barings Bank—one of the oldest financial institutions—began to take on dangerous amounts of risk in response to prior investment losses, and ended up bankrupting the entire firm when his bets resulted in catastrophic losses. Here, we examine several factors that affect how much risk people take and how they respond to prior losses. We derive predictions from a theoretical model based on mental accounting and cumulative prospect theory. Consistent with the model, we find that loss-chasing only occurs when risk is positively skewed and the total number of periods is known. Framing losses as non-gains and risky options as defaults also increases risk taking overall. In our proposed model, people increase risk-taking in response to prior losses when an open (vs. closed) mental account is in the red because they have a strong preference to recoup losses and close the account ‘in the black’ (Thaler and Johnson 1990). Consistent with this model, Imas (2016) demonstrated that people took on more risk after paper losses (Langer and Weber 2008) and less risk after realized losses (Shiv et al. 2005), as realization closes the ‘bracket’ of prior outcomes. In the current paper, we test a more complete set of predictions from the model. Since loss-chasing is driven by the motivation to wipe out prior losses, it should only be observed when the risky prospect offers an opportunity to (at least) break even. People

The Effects of Earmarking on Psychological Spending and Pain of Payment

EXTENDED ABSTRACT

Just as psychological ownership can be a continuum, the boundaries of spending money may not be as clear as once thought. Indeed, psychological spending (the feeling of having spent money) and economic spending (literally transferring the currency due for a good or service) may be significantly separated in time (Prelec and Loewenstein 1998). In the present research, we argue that setting aside money for a specific purchase (i.e., earmarking) begets the sensation of psychological spending. Thus, to some extent, earmarking separates psychological spending from economic spending—psychological spending occurs at the point of earmarking, while economic spending occurs at the point of purchase.

Once people earmark money and incur the psychological expense, they immediately begin adapting to their newly lower amount of money (Gourville and Soman 1998)—in the authors’ original language, the payment is slowly psychologically depreciated. Imagine a consumer faced with additional expenses well after an original psychological expense has been incurred. Because the original payment has been psychologically depreciated, consumers may more freely pursue the new, additional costs. The separation of psychological spending from economic spending also has implications for pain of payment. We show that pain of payment responds to psychological—and not economic—spending, meaning that pain of payment may be transferred from the time of purchase to the time of earmarking, reducing pain upon purchase.

In Study 1, we examine the effect of earmarking on spending non-earmarked funds. Participants (N = 131) were told they received $200 as a gift from an extended family member. Participants were randomly assigned to one of two conditions (Earmark, Control). Participants in the Earmark condition were told they set aside $100 to spend on new clothes, while participants in the Control condition were told they considered spending $100 on new clothes, but hadn’t committed to anything yet. All participants were then asked whether they would use $100 of their gift money to repair their computer, which had recently broken. Even though both groups had $100 in non-earmarked funds, 75% of participants in the Control condition were willing to spend the $100 to fix their computer whereas only 59% of those in the Earmarked condition said they would do so (p < .05). This suggests that participants view earmarked money as spent and thus, they felt they had a smaller budget for other expenditures from the same account, even though no money had actually been exchanged.

In our second study (N = 131), we examine the effect earmarking has in the face of increasing costs. If earmarking is no different from general mental budgeting, individuals should be hesitant to purchase goods when costs are higher than expected: if earmarked funds represent the totality of the account, then increased costs would take individuals “into the red” (Heath 1995). However, if individuals view earmarked funds as already spent, then increased costs a) represent a smaller marginal cost to acquire the good, and b) are in addition to funds that are already psychologically, if not economically, sunk. As a result, earmarking increases the likelihood of purchase in the face of increased costs.
of increasing costs. Indeed, individuals who earmarked funds for a specific purchase were significantly more likely to purchase the good after the price increased than individuals who had not earmarked funds (60% vs. 41%; \( p < .03 \)).

In our first two studies, we showed that consumers who earmarked money behaved as though that money was already spent. In Study 3, we directly examine this feeling of psychological spending. Participants \((N = 50)\) viewed a calendar showing a target car purchase date and rated feelings of already having spent the money for the twelve weeks leading up to the purchase. There was a significant linear trend such that feelings of having spent the money increased as the date of purchase approached \((ps < .01)\). The linear trend was positive for 28 out of 50 participants and negative for only 11 out of 50 participants. These results imply that earmarking leads to greater feelings of having spent money, and those feelings increase as the time of purchase approaches.

In our final study, we investigate how earmarking affects pain of payment \((N = 299)\). In the previous studies we show that earmarked money is more likely to be coded as “spent” than non-earmarked money. If this is the case, then that feeling of psychological spending should reduce pain of payment when the money is spent as intended. Participants were randomly assigned to imagine one of two scenarios: (1) that they had $950 split between a savings account ($350) and a checking account ($600) or (2) that they had $950 split between a savings account ($350), a checking account ($375), and a purchase-specific fund ($225). The second allocation is just a partitioning of the checking account in (1) between a non-earmarked amount and an earmarked amount. Participants were further randomly assigned to consider one of three target products: a book for a friend ($25), a gift for a friend ($75), or car repairs ($200). In all cases, the money in the purchase-specific fund was sufficient to cover the cost of the purchase and was consistent with the intent of the earmarking (e.g., a gift fund for a gift). To measure pain of payment, all participants were asked to rate how painful the purchase was on a nine-point scale \((\text{Not at all painful to Very painful})\).

The results from Study 4 show that purchases across all replicates were significantly less painful in the earmarked condition than in the non-earmarked condition \((P_{book} = .19, P_{gift} < .001, P_{car	ext{-}repairs} = .06\)). Further, a model predicting pain by condition, controlling for replicate, found a significant negative effect of earmarking \((\hat{f}_{\text{earmarking}} = -1.14, p < .001)\). These findings suggest that spending earmarked funds (as intended) is less painful than spending non-earmarked funds.

Overall, our results suggest that the intentions consumers have for how they will use their money affects the perceived value of that money and how that money is used across competing purchases.

Avoiding a Discount to Pay the Full Price: Contingent Promotions Backfire When Redemption is Unlikely

EXTENDED ABSTRACT

“I used to really like those “buy one get one 50% off” tables at the bookstore. I’d browse through it, quickly find a book I liked, and then really push myself to find a “bargain” on another book. The problem was that out of the 30 books on the table, there was really only one I wanted to read.” – The Simple Dollar

Price promotions generally make transactions more appealing (Blattberg and Neslin 1990; Raghubir, Inman, and Grande 2004), swaying consumers to buy from channels offering discounts. However, many price promotions come with a catch. To receive a discount on a focal purchase, consumers may need to first engage in certain behaviors (Inman, Peter, and Raghubir 1997) such as buying multiple items from that channel (e.g. BOGO), buying within a limited time period (e.g. flash sales), or registering for membership in a special group (e.g. loyalty discounts). We categorize all of these deals as “contingent promotions”. Our research explores consumer choices when they don’t wish to do what it takes to qualify for a channel’s contingent promotion (e.g. don’t want to buy two items to qualify for BOGO). We find that consumers are more likely to avoid shopping at channels offering unqualifiable contingent promotions, as buying an otherwise desirable product from that channel is now seen as getting an inferior “deal”.

A body of literature has confirmed that missing an attractive promotion could lead to perceptions of regret and brand switching (Kukar-Kinney, Xia, and Monroe 2011; Simonson 1992; Tykocinski and Pittman 1998; Zeelenberg and van Putten 2005). In this work, we propose that ongoing contingent price promotions can yield similar adverse effects when consumers acknowledge yet don’t anticipate qualifying for these promotions. We use transaction utility theory (Thaler 1983) to explain how contingent price promotions can foster consumer disinterest. Specifically, we predict that consumers aware of a channel’s contingent promotion would feel like they are getting a bad deal if they can’t qualify for the promotion. We hypothesize that a channel offering an unqualifiable contingent promotion can cause consumers to buy a otherwise desired product from a competitor who doesn’t offer a price promotion at all \((S1)\) even if the competitor’s product features are less preferred \((S2)\) or offers the product at a higher price \((S3)\).

Study 1 highlights an instance where consumers seek alternate channels to make a focal purchase when they don’t qualify for a focal channel’s price promotion. Mturk workers were presented two possible places to drink after work (A and B). Place A has happy hour discounts on weekdays, while Place B doesn’t. We find that even though both places offered the same drink at the same price on weekends, participants thought that visiting A that weekend \((M = 4.95; SD = 1.69)\) felt more painful/was a worse deal than visiting B \((M = 5.47; SD = 2.02); t(61) = -2.05, p < .05\) and participants significantly preferred to go to B more \((66.1%; \ z = 2.53, p = .01)\). Study 1 depicts an instance where a channel offering a contingent price promotion can sometimes yield less consumer interest than one that offers no promotion at all.

Study 2 finds that consumers will buy a less preferred product to avoid a product associated with a contingent promotion they don’t qualify for. Participants were asked which hotel out of two choices did they prefer, keeping price constant. We then told participants in the contingent promotion that their preferred hotel gives a welcome gift to loyalty members (participants were not loyalty members) while participants in the control condition were not aware of this promotion. There was a significant effect of condition on hotel choice; when the preferred hotel offered a loyalty member contingent gift, participants chose to book their more preferred hotel at 69.7%, a significant difference from the control condition at 88.1% \((z = 2.50, p = .01)\). Condition type’s effect on hotel choice was mediated by transaction utility of the promoted hotel, indirect effect 95% CI: \([.023, .69]\). Study 2 reveals that in order to avoid feeling like getting a bad deal on a preferred product that comes with an unqualifiable contingent promotion, consumers become more likely to buy a less preferred product that is unassociated with a promotion altogether.

Study 3 finds a case where a channel’s contingent price promotion can drive consumers to buy an identical product from a different channel at a higher price. Mturk participants read that they needed to buy a specific focal product to fulfill an immediate need. The product sells at Store A, which offers a contingent promotion of varying magnitude across conditions (50% off orders over $100;
10% orders over $100; control: no mention of discount) that participants anticipate they can’t qualify for. A similar item currently sells at a higher price at a competitor’s channel (Store B). We found that when Store A offered a contingent, unredeemable promotion, more participants would rather pay more money to buy their needed item with Store B ($^2(N = 320) = 10.57, p < .01, \varphi = .18$), an effect that exacerbated as Store A’s unqualifiable contingent promotion’s discount magnitude increased. We tested whether transaction utility index would mediate the relationship between contingent promotion size and store choice to buy the focal product (PROCESS Macro Hayes 2018; model 4; 5000 bootstrap samples). We found that the indirect effect through transaction utility was significant (95% CI = [.063, .40]) in this model.

Firms should carefully assess the impact of their price promotions. While promotions encourage many customers to buy, they could also deter other groups of otherwise-interested customers. Stores offering a contingent promotion may lead some consumers to seek out competitors’ products (S1), even if that competitor’s product is less preferred (S2), or more expensive (S3).

**Moderators and Extensions of the Interpersonal Sunk-Cost Effect**

**EXTENDED ABSTRACT**

The sunk-cost fallacy—when a consumer pursues an inferior option because s/he has previously invested significant, non-recoverable resources to acquire it—represents a striking, but common, violation of rational decision-making (Arkes and Blumer 1985; Thaler 1980). Recent work uncovered an important variant of this phenomenon: the *interpersonal sunk-cost effect* (Oливіла 2018). Whereas the ‘classic’, *intrapersonal* sunk-cost effect is driven by *one’s own* past investments, the *interpersonal* sunk-cost effect occurs when a consumer alters his/her choice in response to *another person’s* past investments. The *intrapersonal* sunk-cost effect is a robust phenomenon with important theoretical and practical implications (Oливіла 2018). Yet, little is known about its potential moderators or the factors that drive it.

Here, we examine several potential moderators of the *intrapersonal* sunk-cost effect and document a novel, ‘type II’ variant of the effect.

Study 1 ($N_{total} = 1,379$) examined whether the sunk-cost effect is solely driven by the amount of prior investment (i.e., size of the sunk-cost), or also by the amount of social reciprocity/obligations (i.e., number of investors). Specifically, we tested whether adding an (additional) other investor, without changing the total amount invested, would increase the intrapersonal and/or interpersonal sunk-cost effects. Across three different consumer decision-making contexts, we compared responses to a standard intrapersonal sunk-cost (in which the recipient bore the entire sunk-cost) versus a ‘mixed’ intra/inter-personal sunk-cost in which the recipient and another person both contributed (equally) to the prior (sunk) investment, as well as responses to a standard interpersonal sunk-cost (in which one other person bore the entire sunk-cost) versus a ‘multi-person’ interpersonal sunk-cost in which two other people both contributed (equally) to the prior (sunk) investment. Critically, the total size of the sunk-cost was identical across conditions, to avoid confounding number of investors and investment size. We manipulated the presence (vs. absence) of a sunk-cost by having the investment either be refundable (sunk-cost absent) or non-refundable (sunk-cost present). As the dependent variable, participants indicated whether they would pursue the inferior option (i.e., honor the sunk-cost) or abandon it. As expected, they were far more likely to honor the prior investment when it was non-refundable. However, across all three consumer decision-making contexts, adding an other investor (to either the standard intrapersonal or interpersonal sunk-cost), while keeping the total sunk-cost size constant, *did not* increase the tendency to honor the prior sunk-cost. This shows that sunk-cost effects are mainly driven by the size of the prior sunk-cost, and not by the amount of social reciprocity/obligations (i.e., number of investors) involved.

Study 2 ($N_{total} = 1,151$) examined whether the interpersonal sunk-cost effect is driven by an aversion to hurting the investor’s feelings. Specifically, we tested whether the effect would be mitigated, or even disappear entirely, if the investor (the person who bore the prior sunk-cost) passed away before the recipient faced the decision to honor the sunk-cost. Across three different consumer decision-making contexts, we compared responses to a standard (‘investor-alive’) interpersonal sunk-cost (in which the investor was still alive at the time of the recipient’s key decision) versus an ‘investor-deceased’ interpersonal sunk-cost, in which the investor died prior to the recipient’s key decision. Participants imagined that the investor was one of their grandparents. In the ‘investor-deceased’ conditions, this grandparent had died (of natural causes) shortly after making the investment but prior to the key decision, and no one else knew about the late grandparent’s (non-recoverable) prior investment. We also manipulated the presence/size of the sunk-cost. In all three consumer decision-making contexts, the interpersonal sunk-cost effect was directionally smaller in the ‘investor-deceased’ conditions (though the interaction between investor-deceased and sunk-cost size was significant in only one of the three scenarios). Combining data across the three scenarios, we find that the interpersonal sunk-cost effect is significantly smaller, though still significant, when the investor has passed away. Thus, the interpersonal sunk-cost effect is partly, but not entirely, driven by a concern with hurting the investor’s feelings, so that people are less likely to honor large prior sunk-costs when investors are no longer around to potentially learn of this decision.

Studies 3a ($N_{total} = 606$) and 3b ($N_{total} = 604$) tested whether investors also exhibit an interpersonal sunk-cost effect; that is, whether they are more likely to prefer that recipients honor their prior sunk-cost (and pursue the inferior option) when it is large (vs. small/absent).

Study 3a compared, across three different consumer decision-making contexts, the preferences of participants in the role of investors, who imagined having invested either a lot (high sunk-cost) or very little (low/no sunk-cost) to offer a recipient an option that ended up being undesirable. Participants indicated whether, as investors, they would prefer that the recipient (a close friend or family member) continue with this undesirable option (i.e., honor their sunk-cost) or abandon it for a better option. In all three scenarios, participants were more likely to prefer that the recipient honor their sunk-cost when it was large.

Study 3b focused on one consumer decision-making context, but manipulated whether the recipient was a close friend, acquaintance, or stranger, to see whether social closeness (between investor and recipient) would moderate the ‘type II’ interpersonal sunk-cost effect observed in Study 3a. Regardless of social closeness, participants were more likely to prefer that the recipient honor their sunk-cost when it was large. Moreover, there was no main effect of, or interaction with, social closeness.

Taken together, these four studies reveal novel insights regarding the interpersonal sunk-cost effect. First, it is not sensitive to the amount of social reciprocity/obligations (i.e., number of investors) involved. Second, it does seem to be sensitive (in part) to whether the investor may be around to witness (or eventually learn) the recipient’s decision to honor (or not) the sunk-cost. Finally, investors...
also exhibit an interpersonal sunk-cost effect, as they are more likely to prefer that a recipient honor their sunk-cost when it was large, despite the fact that doing so leaves the latter worse off (consuming an inferior option).

SESSION OVERVIEW

As an internal representation of events and concepts (McKellar 1957), mental representation often triggers behavior that is consistent with the content of these representations (Dijksterhuis and Bargh 2001). The mental representation of time is particularly important for our goal achievement (Tu and Soman 2014). For example, the time representations where individuals treat each episode separately instead of connecting them to form an integrative picture often lead to less successful goal attainment (Huang and Hutchinson 2013).

The proposed session brings together four papers that answer two key questions: (1) how do moment-based vs. integrative mental representations of time influence consumers’ goal pursuit processes? and (2) how can we leverage these effects to facilitate consumer goal achievement? The first three papers focus on the effect of the time representations on goal setting and goal activation, and the fourth paper examines the effect on goal fulfillment. In addition, the first two papers mainly focus on the negative impact of moment-based time representations, whereas the latter two papers focus more on the positive effects of considering time in an integrative manner.

The opening paper by Kim et al. investigates in five studies how performing self-regulation influences intertemporal decisions. They find that engaging in self-regulation makes people attentive to time. Consequently, consumers decrease the perceived value of products that will be delivered in the future, increase their willingness to pay for expedited delivery, and evaluate time-related product features as more important.

Second, Duke and Liu examine the effect of photo engagement, compared with merely reflecting on the past, on the activation of long-term goals. They propose and find through four studies that photo viewing promotes a discontinuous moment-based representa-
tion of time that subsequently suppresses long-term goals and choices such as saving, investing, or self-improvement products.

Third, in five studies, Malkoc and Tonietto propose and find that consumers have a different mental representation of gained time (due to a plan change) than free time. Since consumers tend to account for gained time, and it is easier to justify utilitarian (vs. leisure) activities that provide long-term benefits, people are more likely to choose work-like activities with their gained time.

Finally, Huang, Yang, and Morwitz examine in five experiments how planning mode impacts consumer behavior. They find that paper calendars help consumers focus on the global arrangement of the events, whereas mobile calendar interfaces encourage local attention by making people focus on individual days. As a result, paper calendar users develop more efficient plans and implement their plans more successfully.

Overall, these papers provide new insights into how the mental representation of time impacts goal pursuit process using a wide range of research methodologies (longitudinal surveys, field, and lab experiments). The session also addresses the conference theme of Becoming Wise by identifying factors that influence goal achievement. Giving the relevance of these topics to consumers and public policy makers, we believe this session will appeal to a broad ACR audience who are interested in time perception, mental representations, goals, consumer planning, and consumer welfare.

Self-Regulation and Consumer Impatience

EXTENDED ABSTRACT

Intertemporal decisions require consumers to evaluate costs and benefits that occur over a period of time (Frederick, Loewenstein, and Donoghue 2002; Urmisnisky and Zauberman 2015; Woolley and Fishbach 2016). A sales promotion may offer a rebate that will arrive in four to eight weeks. A car dealer may tell a customer that a vehicle can be financed over a period ranging from one to seven years. An on-line retailer may offer delivery times ranging from two to two weeks. These time-based considerations are not inconsequential to decision making. For example, an 84 month car loan at 5% is 7.4% more expensive than a 48 month loan. Amazon Prime, a service originally positioned as a means of expediting on-line orders, had more than 100 million paid subscribers ($99 per year) as of April 2018 (Chowdhry 2018). Thus, time is a managerially and economically important decision variable, and matters to consumers.

This article investigates how acts of self-regulation affect intertemporal consumer decisions. Prior research has shown that acts of self-regulation influence decisions that are situated in the present. Acts of self-regulation encourage impatient behaviors in the present, including impulsive eating (Voils and Heatherton 2000), impulse buying (Voils and Faber 2007), and task disengagement (Laran and Janiszewski 2011). These instances of regulatory failure have been attributed to ego depletion, a state in which executive control resources have been reduced to a level where behavioral control becomes difficult (Baumeister, Schmeichel, and Vohs 2007). We show that acts of self-regulation influence decisions that are situated in the future. Acts of self-regulation reduce the perceived value of products that will be delivered in the future, as well as increase the willingness to pay for expedited delivery. We attribute this intertemporal impatience effect to the increased salience of time. Thus, we extend...
understanding of the influence of self-regulatory behavior into inter-temporal decisions, but do so through an alternative process: time salience.

In Studies 1A-C, participants were randomly assigned to perform either a regulatory or non-regulatory task. They were then asked: 1A) how short or long they perceived three weeks in the future to be, 1B) how much they would be willing to pay for a set of movie passes if they were to receive these three weeks in the future, and 1C) how happy they would be if they were to receive a prize (they have won), three weeks in the future. Participants who performed the regulatory task 1) anticipated the given prospective time interval of three weeks into the future to be longer than those in the non-regulatory condition; 2) assigned significantly lower prices to the delayed product than those in the non-regulatory condition; and 3) reported that they would be less happy to receive a delayed reward than did participants who completed a non-regulatory task.

Study 2 tested the effect of performing self-regulation on impatient consumer choice decisions (express vs. standard delivery). We also compared the effect of self-regulation with that of boredom, which causes time salience temporarily (Eastwood et al., 2012), to examine whether the self-regulation effect persists over time delays. Participants were randomly assigned to one of the 3 (initial task type: non-regulatory, regulatory, boring) X 2 (time delay: no delay vs. delay) conditions. Participants in no delay condition made a choice decision immediately after the initial task, and participants in the delay condition completed a filler task prior to making the choice decision. When there was no delay after the initial tasks, both participants who completed the regulatory task or boring task were more likely to choose the express delivery (i.e., show impatience) than those who completed the non-regulatory task. On the other hand, when a delay was introduced after the initial tasks, participants who completed the boring task were no longer more likely to choose the express delivery option than those who completed the non-regulatory task, whereas participants in regulatory task condition did.

Study 3 examines a different form of consumer impatience: time-related product feature evaluation (Zhong and DeVoe 2010). Participants were randomly assigned to conditions as in Study 2. Participants were then presented with a laptop purchase scenario and were given a list of four features: one time-related target feature (processing speed) and three control features (hard drive size, design, and weight/screen size) and asked to rate how important each feature was to them. Participants in the regulatory and boring conditions both rated the processing speed as more important than did participants in the non-regulatory condition when there was no delay following initial tasks. However, when there was a delay between the initial task and rating attribute importance, participants in the boring condition no longer rated the time-related feature as more important as participants in non-regulatory condition did.

Our findings make two important contributions to consumer research. First, they provide additional insight into the effects of self-regulation by identifying novel consequences (i.e., time salience, an influence on intertemporal judgments). Second, they have the potential to motivate future investigations into how self-regulation and time salience influence judgments involving temporal discounting (e.g., affective forecasting, financial decision making, health-decision making, environmental policy, the value of time-based promotional discounts, sustaining goal pursuit).

Counting Time by Moments: The Effect of Photo Engagement on Goals

EXTENDED ABSTRACT

The advent of smartphones has heralded an era of countless pictures; an estimated two billion photos are shared on Facebook alone every day (Facebook 2015). Fueling this trend, many services exist with the express purpose of showing consumers their own past photographs, such as Timehop, a smartphone app with over 15 million registered users (Kosoff 2015), and Facebook’s “On This Day” feature (Facebook Newsroom 2015), which periodically presents its 1.7 billion users (Facebook Newsroom 2016) with their past photographs. Thus, one’s past is increasingly reviewed through photos rather than mere reflection. How does this frequent photo engagement influence consumers’ cognitions, preferences, and choices?

We propose that photo engagement, unlike natural reflection, uniquely promotes a moment-based, discontinuous mental representation of time. This discontinuous representation suppresses long-term goals. As a result, we propose that viewing personal photos will decrease consumers’ interest in long-term goals such as saving, investing, and improving themselves for their future well-being. Four studies test this theorizing.

Study 1 (longitudinal panel obtained by marketing research firm) tests whether chronic photo-viewing correlates with chronic orientation toward the present (vs. future). US participants (N = 9,406) answered, “If you won a $1000 lottery, how much of it would you spend versus save?” (“Spent $1000 and Save $0” to “Spent $0 and save $1000” in $100 increments). Their detailed demographics (age, gender, income, education, employment, relationship status, ethnicity, housing, state, etc.) were provided by the research firm. Three months later, they answered, “How often do you view photos you’ve taken (on any device)?” (1: A few times an hour when I’m not sleeping; to 6: Rarely). Results revealed a significant negative correlation between photo viewing frequency and saving (vs. spending) orientation (r = -.07, t(9404) = 7.09, p < .001), which persisted even when controlling for all demographics (including strong predictors such as age; β = $28.07, t(1877) = 4.28, p < .001). Frequent photo viewers intended to save less for the future.

Study 2 (N = 246; MTurk) tests for a causal link, demonstrating that personal photo engagement suppresses future-oriented goals. Participants either viewed their past pictures or reflected on the past, and then freely listed their current goals. Three coders blind to condition and hypotheses developed a catalog of themes and coded the responses. Although participants were equally likely to report goals related to family, friends, hobbies, and relaxation (NS), individuals who had viewed their photos became significantly less focused on long-term, utilitarian goals—listing fewer financial (4.1% vs. 14.9%, p < .01), career/educational (7.6% vs. 18.8%, p < .01), and general self-improvement goals (13.1% vs. 28.7%, p < .01). This suggests that future-oriented goals are less salient following personal photo engagement.

Study 3 tests whether the effect on active goals extends to consequential choices. MBA students (N = 192) either viewed their photos from the past six months or reflected on their lives in the past six months. Then, they made two consequential choices. In one, they chose between (a) a future-oriented, career-linked product (Bloomberg Businessweek subscription) or (b) cash; in the other, they chose between (a) a fun magazine (InStyle for F / Sports Illustrated for M) or (b) cash. Photo-viewing did not affect choice of the fun magazine over cash (23% vs. 26%; p = .69), suggesting that it did not simply prime photos or imagery. However, it significantly reduced choice
of the future-oriented magazine (49% vs. 57%; \( p = .048 \)) over cash, consistent with our theorizing.

What drives this effect? We propose that photos differ from unaided memories in their temporal granularity: photos tend to represent events as discrete moments, while natural recall tends to represent events as swaths of time. This moment-based representation leads to a view of time as disconnected, thereby disconnecting oneself from time in the future. We also consider two other explanations: photos might simply be more concrete/vivid than unaided memories, and photos might also capture different content (e.g., fun events) than what is naturally recalled.

To test these competing mechanisms, Study 4 participants (\( N = 372 \)) either (a) viewed personal photos from or (b) reflected on the past 2-5 months and then described the content of the photos they viewed/memories they recalled (“content descriptions”). Thereafter, they reported interest in future-oriented topics (career, retirement, financial health, educational tips, self-improvement) and neutral/entertainment topics (vacation, sports, weather, movies, fashion, games). As before, photos did not influence interest in neutral/entertainment topics (\( M = 4.05 \) vs. \( M = 3.91, p = .26 \)), but significantly suppressed interest in future-oriented topics (\( M = 4.47 \) vs. \( M = 4.81, p = .007 \)). A coder blind to condition and hypotheses coded: participants’ content descriptions for content theme, whether they captured a specific moment versus a moderately to largely expansive swath of time (1 = not specific to 2 = specific), the level of detail provided (1 = none to 3 = extreme), and the vividness (0 = low or 1 = high). Unsurprisingly, there were differences in content: photo (vs. recall) participants were significantly more likely to mention relationships, travel, events, food, pets, self, art, and products, and significantly less likely to mention school, work, and general self-reflection (\( p < .05 \)). However, the content difference did not mediate the effect on future-topic interest. Further, vividness differed by condition (\( p < .001 \)), but also did not mediate the effect. There were no differences in levels of detail. In contrast, only granularity of temporal representation (specific moment vs. expanse of time) mediated the change in interest in future-oriented topics (\( \beta = -.10, 95\% \text{ CI [-21, -01]} \)). Thus, reflecting on the past via photos changes the granularity of one’s temporal representation, thereby changing one’s goal focus.

Future studies aim to bolster this mechanistic evidence.

In summary, while research has begun to explore effects of photo taking (e.g., Barasch, Zauberman, and Diehl 2018; Barasch et al. 2017; Henkel 2014), less is known about the subsequent experience of photo viewing. The current research fills this gap and provide valuable guidance to policymakers and marketers wishing to better understand individual psychology and consumer welfare.

\section*{Spending Gained Time}

\section*{EXTENDED ABSTRACT}

Despite the steady decline in working hours over the last century (Huberman & Minns, 2007), consumers report feeling busier than ever. Further, consumers increasingly outsource their unpaid work, buying services like childcare and housekeeping (Whillans et al. 2017). These trends imply an increase in leisure consumption. However, hours dedicated to socializing have decreased over the last decade (ATUS 2017), potentially because when feeling busy, leisure activities are often jettisoned (Southerton, 2003). We study this paradox by examining how consumers can simultaneously crave more leisure, but do less of it. To do so, we explore how gained time (due to a cancelation or plan change) is consumed and propose that despite a desire for more leisure time, consumers may choose to work when they gain time.

Gaining time creates unaccounted time. Consumers often equate free time with “leisure time” (Unger & Kernan, 1983) believing it is free of obligations and thus will be used in a leisurely fashion. We argue that, when consumers gain time, they do not treat it as free and instead are driven to account for it. Consiously considering how to use time prompts consumers to think about their to-dos. This combined with a desire to enjoy uninterrupted leisure (Tonietto & Malkoc, 2016) might nudge them towards work-like activities.

Study 1 demonstrated this paradox - desiring leisure, but choosing work during gained time. We compared responses to gaining time during the same day to an unspecified future date. Unlike the present or near future, the (unspecified) future is often decontextualized from our daily demands (Zauberman & Lynch, 2005). As such, we expected when participants considered an unspecified future time that they would treat it as free and indicate a desire for leisure. However, when they gained time during the context of the same day, consumers would consider their to-do list and thus prefer work tasks.

175 undergraduates imagined either having gained a few hours in the next couple of weeks or later in the same day and indicated how they would spend this time (1=definitely leisure; 9=definitely work). We also measured participants’ perceived time famine and their desire for more work and leisure in their life. Unsurprisingly, participants reported experiencing time famine (\( M=4.79, p<.01 \) compared to the midpoint of the scale). They also wished they had more leisure (\( M=5.06 \)) than work (\( M=3.83, p<.01 \)). Further, reported time famine was positively correlated with desire for more leisure (\( r = .28, p<.01 \)), but uncorrelated with desire for more work (\( r = -.03, p = .63 \)). Thus, it appears that participants crave more time to increase leisure consumption. However, comparing the consumption of specific and context-free time, we found that participants who considered gaining time that same day preferred work-like tasks (\( M=7.27 \)) compared to those who considered gaining time in the context-free future (\( M=5.27, p<.01 \)). Importantly, participants’ desire for more leisure did not predict their intended behavior in either condition (both \( p > .90 \)).

Next three studies compared gained time to time that was always free. In study 2, 153 MTurkers either imagined having 1.5 hours of free time that evening or unexpectedly gaining 1.5 hours that evening and reported how they would prefer to consume this time (1=fun and enjoyable tasks; 9=work-related task). As expected, we found that participants were more likely to choose work-like tasks when they gained time (\( M=3.17 \)) than when they had time free (\( M=2.44, p<.05 \)).

Since our studies rely on a certain level of specificity, in Studies 3 and 4 we examined whether differences in construal level (Trope & Liberman, 2010) account for our results. In Study 3, we used specific work/leisure descriptions and manipulated temporal distance. 342 undergraduates imagined having/gaining 1.5 hours either that evening or the same evening in one week and indicated their task preference (1=catch up with friend/family/neighbor; 9=catch up on errands/housework/chores). Note, that unlike study 1, participants in the distant future condition thought of a particular day in the future where they are likely to have context such as their usual work load for that time of the week. Once again, we found that participants who gained time preferred a work-like task (\( M = 5.46 \)) compared to those who had time free (\( M = 4.71, p<.01 \)). Importantly, there was no main effect nor interaction of temporal distance (both \( p > .2 \)). Thus, temporal distance that includes context is not sufficient to moderate the effect. To examine construal level from a different angle, in Study 4, we manipulated participants’ mindset. Before indicating their preference (1=fun and enjoyable task; 9=work-related task), participants thought about why they would choose a work/leisure activity or how
they would go about engaging in a work/leisure activity. As before, we found that participants who gained time preferred work-like tasks (M=5.09) compared to those who had time (M=4.03, p<.01). Importantly, the how/why manipulation did not produce a main effect nor an interaction (both p>.1).

We next sought to provide evidence for our proposed account by measuring a preference to prioritize work. To rule out consumers’ reluctance to engage in leisure during short periods of time, in study 5, we also used a 3-hour period. 202 participants imagined having or gaining 3 hours the same evening and indicated their activity preference (1=fun and enjoyable task; 9=work-related task). Next, we measured hyperopia, as well as participant’s desire to prioritize work (i.e., I’d rather get some work tasks out of the way). As before, participants who gained time were more likely to prefer a work-like task (M=2.83) than those who had time (M=2.17, p<.05). This effect remained significant when controlling for hyperopia. Importantly, we find that participants’ desire to prioritize work moderated the effect, where participants who prioritize work to a greater extent (r=.27 standard deviations from the mean or higher) showed greater preference to work during gained (vs. free) time.

In sum, despite their desire to increase leisure in their lives, consumers may paradoxically prefer to work when given extra time in their day. This is because while gaining time creates free time, gained time is categorically different from free time.

Helping Me See the Whole Picture: How Using a Paper versus Mobile Calendar Influences Consumer Planning and Plan Fulfillment

EXTENDED ABSTRACT

With today’s busy lifestyle, consumers often use various planning tools to help them set and fulfill plans. Creating schedules using a calendar is one common planning method that helps consumers manage their time (Kaufman-Scarborough and Lindquist 2003) and employees increase their work efficiency (Parke et al. 2018). With the prevalence of smart technology, many consumers use calendars on mobile devices. However, print calendars still thrive and attract the prevalence of smart technology, many consumers use calendars to manage their time (Kaufman-Scarborough and Lindquist 2003) and a calendar is one common planning method that helps consumers organize and prioritize activities will often be implemented more successfully (Dean and Sharfman 1996; Smith et al. 1990). We tested our hypotheses in five studies.

Studies 1-2 demonstrated the main effect that plans made through paper (vs. mobile) calendars are perceived as more effective in helping consumers see a big picture of the events. Study 1 (N = 352) was exploratory where participants indicated what types of calendar they use for their everyday planning and how they perceive using each type. Although more participants reported using mobile (vs. paper) calendars (57% vs. 32%, p<.01), they believed paper (vs. mobile) calendars facilitate seeing a whole picture when planning (measured through four items: “helping me see a whole picture when planning,” “is an effective way to sort out what should be done,” “easier to organize the tasks,” and “effective in achieving the planning purposes.” (Cronbach’s α=.96; M_paper = 7.38 vs. M_mobile = 7.09; p<.05).

Study 2 (N = 147) replicated the effect using a specific planning task where undergraduate students were randomly assigned to make a week-long study plan using either a paper or a mobile calendar, and then answer questions about their plans. Participants who used paper (vs. mobile) calendars thought their plan was more effective (M_paper = 6.84 vs. M_mobile = 6.24; p<.05).

Study 3 (N = 129) tested the effect of calendar type on plan execution. Undergraduate participants were randomly assigned to either the paper or mobile calendar condition toward the end of the semester. They were asked to (1) plan for a study session for a self-selected course, (2) think of one leisure/relaxing activity, and (3) add both events to their calendars for the next two weeks. Participants were recontacted two weeks later and answered questions about their plan execution. A higher percentage of participants in the paper calendar condition (72.5%) than in the mobile calendar condition (47.8%) completed either the study or the leisure activity (p<.05).

Study 4 (N=553) replicated the effect on plan implementation and provided process evidence. Participants were asked to plan for the next 10 days on either a paper or a mobile calendar. They also thought of one thing that they often think about doing but haven’t found a chance to do (e.g., read a book, exercise, etc.), and then scheduled this activity into their calendar. Their plan perception was also measured. Participants in the paper (vs. mobile) calendar condition again thought their plan was more effective in helping them see a big picture (M_paper = 7.28 vs. M_mobile = 6.94; p<.05). Also, replicating study 3, a higher percentage of those in the paper (vs. mobile) calendar condition completed their specific scheduled task (83% vs. 72%, p<.05.). Participants also indicated the extent to which they fulfilled their overall calendar plan during the last 10 days (Parke et al. 2018). Those in the paper calendar condition had more effective plan execution than those in the mobile calendar condition (M_paper = 7.45 vs. M_mobile = 6.90; p<.05), and this greater implementation was mediated by the perceived effectiveness of the plan (95% CI: [0.10, 0.46]).

Study 5 (N=505) provided further process support by priming global (vs. local) focus by asking participants to work on a shape task based on the overall form (vs. individual elements) in pictures (Gasper and Clorie 2002). We later measured participants’ self-induced plan execution. As expected, there was an interaction effect between calendar type and global-focus manipulation (p = .05). Specifically, those with a paper calendar implemented their plan to a similar extent regardless of the big picture manipulation (M_global = 7.31 vs. M_local = 7.34; p> .90). However, those with a mobile calendar were more likely to fulfill their plan when being primed to focus on “big-picture” (M_global = 8.05 vs. M_local = 7.26; p<.01). The interaction effect was mediated by the perceived plan effectiveness (95% CI: [0.04, 0.49]).
In conclusion, we find that a plan created through a paper (vs. mobile) calendar is perceived as more effective in facilitating seeing a big picture of the scheduled event, which, in turn, leads to a greater likelihood of plan execution.

174 / Discrete vs. Connected: How the Mental Representation of Time Impacts Goal Pursuit and Goal Fulfillment

Technological advancements have transformed the ways in which consumers engage with companies over the past years. These changes have posed new challenges for marketers, who need to adapt to novel means of reaching, engaging and ultimately persuading consumers—whether through online advertisement, social media communication, or virtual reality. This special session addresses important theoretical and substantive questions regarding the effectiveness and implications of novel persuasive tactics in the ever-evolving technological landscape. In particular, the first two papers compare the persuasive consequences of using virtual reality and audience partitioning, while the third and fourth paper compare different types of persuasive appeals (i.e., appeals that reference change and rivalries).

Kristofferson, Daniels and Morales focus on a novel and understudied persuasion medium: virtual reality. They compare the persuasive consequences of using virtual reality and 360° 2D views in charitable appeals. They find that viewing a charitable appeal in VR (compared to 360° 2D views) increases engagement with the appeal’s message and subsequently heightens empathy and support for the cause. Yet, very intense VR appeals can cause consumers to disengage as a self-protection mechanism.

Valsesia, Diehl and Nunes introduce audience partitioning as a novel persuasion approach in one-to-many communication that divides audience members into addressed and non-addressed recipients. They find non-addressed recipients are more persuaded by a persuasive message addressed at someone else (for instance, a social media post tagging another user) compared to those who are addressed implicitly (those reading a social media post without tags) or explicitly (those tagged in the post).

Kupor, Jia and Tormala examine what types of persuasive appeals can break through the clutter of online advertisements and heighten click-through rates. They find that appeals that reference change (e.g., a change in recipe) can boost consumer curiosity, trigger information-seeking, and heighten behavioral intentions. Importantly, the positive effects of references to change on behavioral intentions depend on consumers being able to review information about the change. Those who cannot prefer entities that have not changed.

Costello, Walker Reczek and Smith investigate what types of persuasive appeals induce consumers to engage in risky behaviors. They find that promotional appeals that feature rivalries unrelated to the brand (e.g., Ohio State vs. Michigan) can invoke a ‘rivalry mindset’, which lowers risk perceptions and causes consumers to take risks (e.g., try a risky product or share personal information on social media). This effect is particularly strong among consumers highly invested in one of the referenced rivals.

All papers are at an advanced stage of completion with multiple studies completed. Taken together, they shed light on novel persuasive tactics that leverage the changing landscape in technology and communication. In the spirit of the conference theme of expanding traditional media-types is scant. This research seeks to take the first step in understanding the opportunities and limitations of this emerging technology.

We predict that viewing a charitable appeal in VR can increase subsequent support for the cause compared to viewing the same appeal in two-dimensional (2D) formats. Importantly, we identify engagement with the appeal’s message as the psychological process through which VR increases empathy and subsequent support (Diehl, Zauberman, and Barasch 2015). However, drawing on research on information avoidance (e.g., Golman, Hagmann, and Lowenstein 2017), we argue that VR’s empathy-inducing potential has limits. We propose that appeals with extreme content designed to elicit strong reactions will hinder consumer engagement with the appeal.
as a means to cope with the content, and mitigate any downstream benefits on subsequent cause support. In all studies, we contrast a VR appeal with a 360-degree 2D medium and measure actual donation behavior. Thus, both formats are novel, cutting-edge tactics currently being explored by marketers, yet never tested theoretically for effectiveness.

Study 1 demonstrates that appeals viewed in VR (vs. 2D) elicit significantly higher donations. Undergraduates (n=203) received a $5 bonus for completing this study in addition to course credit and were run individually. Participants watched an appeal in VR or 2D from SmileTrain, a real children’s charitable organization that offers free cleft repair surgery for children in impoverished nations. The appeal featured the story of a young girl in India and the impact the surgery had on her life. Upon completion, participants were given the chance to donate their $5 payment to the organization. As predicted, participants donated significantly more money when they viewed the appeal in VR vs. 360-degree 2D (MVR = $2.25 vs. M2D = $1.60, p < .05).

Study 2 shows support for our engagement process claim. Undergraduates (n=123) participated in this study in exchange for $5. Participants watched an appeal in VR or 2D about a real non-profit endangered species conservation organization. The appeal featured a baby rhino drinking her morning bottle and was uplifting in nature. Engagement was assessed by recording and coding automatic happiness responses (sessions video recorded and behavioral engagement coded 1-7). Upon completion, participants were given the chance to donate their $5 payment to the organization. As predicted, VR led to higher engagement than 360-degree 2D (MVR = 3.00 vs. M2D = 1.39, p < .001). Importantly, a larger percentage of participants in the VR condition (65.2%) than the 2D condition (38.6%) donated to the conservation organization (p < .01).

Study 3 examines the limitations of VR in charitable appeals. We propose that the extremity of negative content will moderate the relationship between media type and message engagement such that extremely intense charitable appeals in VR will inhibit message engagement. This is because the intense negative content in the VR appeal will cause consumers to react defensively and disengage with the message in the appeal as a self-protection mechanism (Taylor and Brown 1988). Study 3 tests this prediction using actual and edited versions of a real non-profit’s VR campaign (Tree 4 Hope) created to raise funds to build a school for impoverished and abused girls in Guatemala. The audio message of the appeal was extremely intense in nature. We collaborated with the charity and changed their actual appeal to test our theoretical framework and predictions by creating an appeal of moderate intensity (content facts were consistent across appeals). As such, study 3 employed at 2(media type: VR, 2D) x 2(message extremity: high, moderate) design.

Participants (n=420) viewed either the actual (high message extremity) or edited (moderate message extremity) appeal in VR or 2D in exchange for course credit. Upon completion, participants completed engagement and empathy measures. Finally, participants were provided with a $2 bonus and given the opportunity to donate to the charity. The 2x2 ANOVA on engagement yielded the expected interaction (p = .001). When message extremity was moderate, VR led to higher engagement than 2D (p < .001); however, the benefits of VR were blunted when the extremity of the appeal was high such that no differences emerged between the two media types. As predicted, higher engagement led to stronger empathetic responses (p < .001), which in turn increased actual donations (p = .001). The extreme appeal (the charity’s actual appeal), however, eliminated the engagement benefits of VR, mitigated the emotional responses, and did not increase subsequent donation behavior.

In conclusion, we examine the potential implications that virtual reality technology can have in the cause-marketing industry. We demonstrate both the potential opportunities and limitations of using this emerging medium in charitable appeals, and highlight the key psychological role that message engagement plays. By forcing the viewer directly into the perspective of cause recipients, virtual reality has the potential to elicit stronger responses and support than charitable marketers previously thought possible. However, without careful calibration, forcing donors to walk a mile in a cause recipient’s shoes may lead them to close both their eyes and their wallets.

**Persuading the Bystander**

**EXTENDED ABSTRACT**

It is increasingly common for consumers to be exposed to persuasive attempts in the context of one-to-many communication, both on- and offline. One-to-many communication presents distinct communicative challenges, but also opens the door for the communicator to use new tactics to achieve her persuasion goals.

Imagine, for instance, a social media user scrolling through her Instagram feed and seeing a post by a beauty influencer, praising the benefits of a new detox smoothie. Similarly, imagine a consumer standing in line at an ATM machine when a volunteer from a non-profit organization approaches trying to collect signatures for a petition. In both cases, the communicator’s intention to persuade will likely be apparent to the consumer and this persuasion knowledge might be enough for the consumer to raise cognitive defenses as a way of dealing with the persuasive attempt (Fiestad and Wright 1994; Rule, Biais, and Kohn 1985; Schank and Abelson 1977; Campbell and Kirmani 2000). What happens if, instead, the consumer is simply a bystander to a persuasive attempt addressed to someone else? Consider, for instance, the situation when the influencer chooses to address her (still public) social media post to one of her friends (by means of tagging her) or a consumer listens in as the petitioner addresses another consumer in line.

What has changed in these scenarios is the participation structure of the influencers’ and the petitioner’s audiences (Goffman 1959, 1981; McGregor 1986). The participation structure of an audience describes the roles played by the various audience members. One way in which a persuasion agent can change participation roles is by dividing audience members into two categories: addressed recipients and non-addressed recipients. We refer to this as audience partitioning. When the audience is partitioned, those not addressed become bystanders to a communication addressed at someone else. In this work we argue audience partitioning can be an effective persuasion tactic in one-to-many communication and that bystanders would be more likely to be persuaded to try a detox smoothie or sign a petition compared to members of the addressed audience. We find that, when being exposed to a persuasive attempt addressed at someone else, consumers have lower barriers to persuasion than they would if they were members of the addressed audience. In other words, the persuasive message is met with lower skepticism and its persuasive effectiveness is greater.

Study 1 (N=248) tests the prediction that audience partitioning affects the efficacy of persuasive attempts. Respondents were asked to imagine they were at a bike store and heard another customer asking a sales assistant about road bikes. We manipulated Audience Partitioned by telling respondents that they either heard the conversation between the other customer and the sales assistant, or joined the conversation. Attitude towards the bike recommended by the sales assistant was significantly more positive when the audi-
ence was partitioned as opposed to not partitioned ($M_{Partitioned}=6.04, SD=1.29$, vs. $M_{NoPartitioned}=5.67, SD=1.48$, $F(1, 246)=4.28$, $p<.05$).

Study 2 replicates the findings of study 1 in a different persuasion setting. Two hundred and six college students read a scenario about being in line to withdraw some cash at the ATM machine, with another person in line behind them. We manipulated Audience Partitioned by telling respondents that a petitioner either approached the person behind them or approached both them and the person behind them. All respondents then listened to an audio file of the message the petitioner used to try and convince her audience to sign a petition to introduce exam retakes in their school. Attitudes towards retakes were more positive when the audience was partitioned and respondents were bystanders to the persuasive attempt ($M_{Partitioned}=7.15, SD=1.82$, vs. $M_{NoPartitioned}=6.43, SD=2.25$, $F(1, 204)=6.43$, $p<.01$).

Study 3 (N=220) replicates these findings in yet another setting while also providing evidence of process. Participants were asked to imagine being at a store and either being approached by a sales assistant alongside another customer or listening in to the sales assistant approaching another customer. They were then exposed to a sales pitch for a new multi-vitamin supplement. Attitudes towards the supplement were more positive when the audience was partitioned ($M_{Partitioned}=5.54, SD=1.76$, vs. $M_{NoPartitioned}=4.99, SD=2.86$, $F(1, 218)=5.03$, $p<.05$). Moreover, we measured persuasion knowledge activation (Kirmani and Zhu 2007) and found respondents were less skeptical towards the sales assistant when the audience was partitioned ($M_{Partitioned}=2.60, SD=1.78$, vs. $M_{NoPartitioned}=5.50, SD=1.94$, $F(1, 218)=11.23$, $p<.001$). Skepticism mediated the effect of audience partitioning on attitudes ($b_{partial}=.51, 95\% CI [.200;.852])$.

Study 4 (N=600) shows a boundary condition of our effect, while shading further light on the mechanism at play. If audience partitioning does indeed decrease barriers to persuasion, bystanders should elaborate a persuasive message more thoroughly and therefore be more persuaded only when the persuasive appeal contains a relatively strong (vs. weak) argument. We therefore ran a 2 (Audience Partitioning: Yes vs. No) x 2 (Message Strength: Strong vs. Weak) between-subject study. Respondents read the same scenario of study 3 and rated their attitudes towards the multi-vitamin supplement after being exposed to an appeal pre-tested to be either strong or weak. We find that attitudes towards the supplement were more positive when the audience was partitioned if the sales assistant made a strong argument ($M_{Partitioned}=6.04, SD=2.13$, vs. $M_{NoPartitioned}=5.43, SD=2.03$, $F(1, 596)=6.80$, $p<.01$) but not if he made a weak argument ($M_{Partitioned}=2.93, SD=1.96$, vs. $M_{NoPartitioned}=2.96, SD=1.93$, $F(1, 596)=.02$, $p=.88$, with $F_{excluded}(1, 596)=3.38$, $p=.05$).

This work is the first to investigate how audience partitioning could be used strategically to affect persuasion. In doing so, it contributes to the literature on persuasion and social influence by documenting a novel persuasive tactic that can be of interest to both researchers and practitioners alike. Moreover, it contributes to the literature on social cognition and communication, which has yet to investigate empirically whether, when and how people manage the participation structure of an audience in the context of persuasive communication.

Changes to Clicks: References to change break through the clutter and promote persuasion

EXTENDED ABSTRACT

Significant literature shows that consumers exhibit a longevity bias and prefer products that have existed in their current form for a longer duration (e.g., Eidelman and Crandall 2014). In contrast, we document systematic conditions under which persuasive appeals cause consumers to prefer products that are framed as having less longevity. Specifically, we find that references to change in products not only prompt consumers to infer that those products have less longevity, but also—when consumers can search for further information about those products—trigger consumers to seek additional product information, which enhances consumers’ preference for those products when this information search leads consumers to encounter compelling information about those products’ benefits. This research answers a critical question that marketers face in the digital marketplace: How to motivate consumers to learn more about the products that they promote.

Study 1 tested our predictions in the field by launching online advertisements. The advertisements urged consumers to click on them to learn more about the cholesterol guidelines, and varied only in whether they indicated that these guidelines had changed. We examined the impact of this change reference on click-through rates: Click-through rates are a widely used measure of online advertising effectiveness (Forrester 2002), and a primary determinant of whether consumers click on online content is whether that content evokes curiosity (Alves et al. 2016). As predicted, the ad which noted that the guidelines had (vs. had not) changed generated a greater click-through rate, $\chi^2 = 11.11, p < .001$.

Study 2 tested the proposed mediating role of curiosity. Participants read the beginning of a report describing Gaia granola, and this information varied only whether it indicated that Gaia’s granola recipe had changed. After indicating their curiosity in reading the rest of the information, participants made a real choice about whether to view the rest of the information. Participants who chose to view the additional information then viewed actual Gaia promotional information (Gaia 2018). Participants who read that Gaia granola did (vs. did not) change were more curious ($\chi^2(4, N=415) = 3.98, p < .001$), more often chose to view the rest of the information ($\chi^2(df = 1, N=415 = 21.84, p < .001)$, and were more likely to purchase it ($\chi^2(4, N=413) = 2.66, p = .008$). A serial mediation model with bootstrapping revealed that the reference to change fostered more favorable behavioral intentions because it heightened curiosity, and thus prompted greater information seeking (95% CI .2708, .6628). Studies 3–4 documented the generalizability of this phenomenon by replicating it in two different domains: tourism and holiday shopping deals.

Importantly, participants also perceived the changed (vs. unchanged) entities in all studies as having less longevity (ps < .004). Study 5 reconciles the current findings with the longevity bias, which indicates that people often prefer entities that have existed in their current form for a longer duration (e.g., Eidelman and Crandall 2014). The longevity bias has been documented in contexts in which consumers cannot choose to view additional information about the focal entity; within these constraints, we predict that the longevity bias causes consumers to prefer unchanged products that have existed in their current form for a longer duration as a result of the absence of change. By contrast, when consumers are able to seek further information about products if they wish—as is often the case in the real world—we theorize that the opposite can occur. We tested this prediction in Study 5.

In Study 5, participants read the first sentence of a report noting that Target’s warranty policy either had or had not changed, and then chose whether to view information about the policy. Participants who chose to view this information were then randomly assigned to either view their chosen information (which contained strong arguments about the policy’s benefits), or to read that they could view the information later. As predicted, a 2 (Change Reference: No vs. Yes) × 2 (Information Available: No vs. Yes) binary logistic regression on the choice data revealed that participants more often chose...
to view the information when the policy had (vs. had not) changed ($p < .001$). Also as predicted—because the information availability manipulation occurred after participants made their information choices—there was no main effect of this subsequent manipulation ($p = .888$), and no interaction with this subsequent manipulation ($p = .349$). In addition, a $2 \times 2$ ANOVA on participants’ intentions to shop at Target revealed an interaction $F(1, 796) = 15.09, p < .001$: When participants did not view the additional information they selected before reporting their behavioral intentions, participants had more favorable behavioral intentions when they read that Target’s policy had not (vs. had) changed ($p = .012$). By contrast, when participants viewed the additional information they selected before reporting their behavioral intentions, the reverse pattern emerged ($p = .003$).

Advertisers fiercely compete to motivate consumers to click on their advertisements in order to nudge them along the path to purchase. Advertisers often have the option to highlight aspects of products that have either changed or that have longevity (i.e., that have not changed for a substantial duration). This research is the first to find that framing messages around the notion of change can stimulate the consumer reaction for which advertisers frequently compete: the curiosity to learn more. We further find that the resulting change-induced information search can increase persuasion when consumers’ information search leads them to encounter compelling information about the focal entity’s benefits. However, because references to change not only spark curiosity but also signal that the changed entity has limited longevity, references to change can have the opposite effect when additional (compelling) information about the changed entity is unavailable. Thus, we both uncover a novel source of curiosity and also advance the longevity literature by illuminating conditions under which the reverse phenomenon emerges. In sum, framing messages and offerings around the notion of change can enhance their persuasive appeal by stimulating a precious cognitive reaction: the curiosity to learn more.

**Risk and the Rivalry Mindset: Promotions Involving Group Rivalries Increase Risky Consumption Behaviors**

**EXTENDED ABSTRACT**

Although marketing promotions commonly feature rival brands (e.g., Coke vs. Pepsi), marketers may also choose to invoke rivalries unrelated to a brand in promotions in an attempt to increase consumer engagement (e.g., 7-Eleven’s Coffee Cup Election Day promotion, where participants can choose a Republican or Democrat coffee cup). Despite the use of these types of rivalry promotions in the marketplace, little is known about when and why this strategy may be persuasive to consumers. In this research we argue that rivalry promotions may be particularly effective when a brand wants consumers to engage in a risky behavior (e.g., trying a risky product, giving up one’s personal information to a brand, etc.).

Research on rivalry in organizational behavior has shown that competition against rivals leads to riskier strategies in an effort to win (Converse and Reinhard 2016; To et al. 2018). We propose that even when a rivalry promotion features no opportunity to win, such promotions can lead to risky behaviors merely by referencing the rivalry because they invoke a “rivalry mindset.” We suggest that this mindset encourages consumers to think of themselves in terms of their membership within the group involved in the rivalry, leading to decreased perceptions of risk to the self (Chou and Nordgren 2018; Park and Hinsz 2006). Consistent with the literature documenting spillover effects of mindsets (Gollwitzer et al. 1990; Wyer and Xu 2010), we predict that exposure to rivalry promotions can thus lead to subsequent risky behavior in contexts unrelated to the original promotion. Finally, we predict that this effect is strongest for those with high levels of group self-investment (Leach et al. 2018) for the group involved in the rivalry.

In Study 1 ($n = 248$) we test whether rivalry promotions increase interest in a risky product using a 2 (Promotion Type: Rival vs. Non-Rival) x 2 (Product Type: Risky vs. Non-risky) between-subjects design. Participants in all conditions engaged with a promotion that involved matchups for the focal university’s basketball team. Promotion type was manipulated by featuring either a rival of the university where the study was held or a non-rival in the school’s athletic conference. The promoted product was either Lay’s Potato Chips (non-risky) or Lay’s Mystery Flavor Potato Chips, an unknown and unusual chip flavor (risky). All participants first viewed a promotional display referencing the chips as a snack for watching an upcoming game and then completed a social media post about the promotion. Next, all participants indicated how likely they would be to look for the promoted potato chips in the grocery store. Analysis yielded our predicted interaction ($F(1,243) = 4.61, p = .03$). Participants were significantly more interested in the risky mystery chips in the rivalry condition ($M_{Rival} = 3.42, M_{Nonrival} = 2.65$; $F(1, 243) = 5.94, p = .016$); interest in non-risky chips did not differ by promotion type ($M_{Rival} = 4.75, M_{Nonrival} = 4.95$; $F(1, 243) = .38, p = .54$).

In study 2 ($n = 298$) we again manipulated whether a promotion focused on a rival or a non-rival school and examined how this influenced participants’ choice of a risky or non-risky reward. We allowed participants to allocate six rewards coupons that either guaranteed $1 off a future Chipotle order or that offered an entry into a lottery that offered a 10% chance to win a $10 gift card to Chipotle. As expected, individuals in the rivalry promotion condition allocated significantly more of their rewards to the risky option ($M_{Rival} = 2.09, M_{Nonrival} = 1.61$; $F(1,295); p = .026$).

In study 3 ($n = 171$) we use a non-sports rivalry and employ the sharing of personal information with a brand as our measure of risky behavior. We also test whether the rivalry mindset can carry over to risky behaviors involving brands unrelated to the original promotion. To do so we conducted an experiment on Election Day 2018 inspired by a real 7-Eleven promotion. Depending on condition, participants either engaged in a promotion referencing the Democratic and Republican parties (rivalry condition) or the fall season (control condition). In the rivalry condition, participants chose a coffee cup representing their preferred political party and made a social media post with the cup and a caption about the rivalry. In the control condition participants picked a cup with their favorite fall color and wrote a post about why this cup is their favorite. Participants then imagined they walked to another aisle and saw a display advertising a sweepstakes for their favorite candy. They were told that they could earn additional entries into the sweepstakes by sharing personal information with the brand. Participants then provided their likelihood of sharing six pieces of personal information (e.g., email, race). Analysis indicated a significant effect of promotion ($F(1,168) = 4.48, p = .036$): Individuals who engaged in the rivalry promotion were significantly more likely to provide personal information ($M_{Rival} = 4.49, M_{Nonrival} = 4.02$).

In study 4 ($n = 203$) we test the mediating role of risk perceptions and the moderating role of group self-investment. Participants were told their team was playing a televised football game against a rival or non-rival school, and that Johnsonville Brats had partnered with the pregame show and was asking fans “to create signs trash talking [school name] and its fans using #bringtheheat.” Participants wrote a post about why this cup is their favorite. They were told whether they could provide six pieces of personal information to Johnsonville in an online form. Next they answered two questions measuring risk perceptions to the
self and three questions measuring group self-investment (Leach et al. 2008). Regression analysis revealed a significant interaction between promotion condition and group-self investment on number of pieces of information shared ($β = .20, p = .047$). Johnson-Neyman analysis revealed that rivalry promotions lead to significantly more information shared for those high in group self-investment. Mediated mediation analysis using PROCESS model 7 (Hayes 2017) showed that for those with a high level of group self-investment, risk perceptions significantly mediated the amount of personal data shared, with lower risk perceptions leading to more shared data.

SESSION OVERVIEW

This session explores whether, when and why the marketplace decisions of product owners are influenced by their relationship with the possession. The history of a possession can make it special or cherished to owners, who become emotionally attached and develop a strong possession-self link—and this can influence owners’ preferences when consumers are disposing of their possessions (e.g., renting, donating). Similarly, situational factors and conditions may serve as triggers that impact owners’ decisions to dispose of a possession. Specifically, this special session will address the following issues:

Research by Li and Janiszewski explores how an object’s history can influence owners’ willingness to share their possessions with others in the sharing economy, and the price they set. Three studies document these effects and draw implications regarding how sharing platforms can increase supply, facilitate matching of idiosyncratic supply and demand, and grow the sharing markets. Research by Graul, Brough and Isaac finds that owners in consumer-to-consumer rental contexts prefer users who engage with their product less (vs. more) and attributes the effect to a concern for wear-and-tear minimization in contrast to enjoyment maximization. This effect is moderated by the strength of owner attachment as well as whether the rental platform mitigates the financial risk of damage. Research by Dunn, White and Dahl presents five studies showing that reminders of one’s own mortality can lead to materialistic and self-serving behaviors to explore a condition under which mortality salience leads to increases in giving away one’s own possessions—when the donation act is high in transcendence potential. Research by Weiss questions whether the strength of consumers’ attachment to a possession always affects their decisions about it and shows that consumers primed with a product-independent (vs. product-dependent) identity overlook the strength of their possession-self links; they therefore replace the use of their possessions with the use of rentals.

Together, all four papers in this session offer novel insights by examining the role of self-connections to possessions created by a possession’s attachment history and whether, and why it affects an owner’s decision to temporarily or permanently part with the possession. Discussion following the special session is expected to appeal to a wide academic audience, including those interested in possession attachment, identity, meanings, and transformative consumer research. As the recirculation of used goods becomes increasingly feasible with technological advances and important to environmental preservation, self-connections to possessions and their influence on owner decisions in the marketplace will continue to receive attention from consumer researchers.

Object History Value Shapes Owner Decisions in the Sharing Economy

EXTENDED ABSTRACT

The emerging sharing economy, especially online-platform-enabled peer-to-peer (P2P) rental, enables consumers to rent their personal possessions to others for a fee or access goods that other consumers own. For example, a person can rent a neighbor’s car on Turo, a traveler can rent a spare bedroom in a host’s home through Airbnb, an amateur filmmaker can rent a range of camera gear from professionals through ShareGrid, a college senior can rent a high-quality interview outfit from a business person though Style Lend. The quantity and price of shared goods in these markets depend on the willingness to share of owners with valuable possessions; and the matching of idiosyncratic supply and demand is the key to sharing platforms’ success. We propose that the concept of object history value can help us better understand the sharing dynamics.

Owners assign history value to their possessions given the history the objects have witnessed, for example, how it was acquired, in what occasion it was used, who have used it, etc. Because object history value lies in one’s perceived association between the object and its history, according to association theories (Anderson, 1988; Raaijmakers & Shiffrin, 1981; van Osselaer & Janiszewski, 2001; Zhang, Fishbach, & Kruglanski, 2007), we propose that 1) an object’s history value is positively correlated with the meaningfulness of the history to which it is connected; 2) the object carries history cues or is a cue itself to the history with which it is associated, and the presence of the cues makes history value salient in one’s valuation of the object in relation to other attributes; and 3) history value can be strengthened or diluted based on the association strength between the object and the history. In a P2P sharing setting, in particular, the owner and the renter can individually or interactively contribute to an object’s history value, which influences the owner’s willingness to share and price to set for a particular rental.

Study 1 tested, in a car-sharing context, whether owner-created history value will make owners less likely to rent their possessions, and whether removing history cues can increase the likelihood to rent with a 2(history meaningfulness: high vs. low) by 2(cue presence: present vs. absent) between-participants design. Participants imagined owning a 10-year-old car with visible dents and stains (cues) which were associated with either meaningful family memories or meaningless events, and these cues were either present or removed through renovation when participants were asked how likely they would list the car for sharing (1 not at all likely -7 very likely). We observed a two-way interaction ($F(1, 297) = 3.99, p = .047$); when cues were present, owners were less likely to share when the history was meaningful ($M_{high} = 3.88, SD = 1.92; M_{low} = 4.99, SD = 1.81; F(1, 297) = 12.65, p < .001$); when cues were absent, however, own-
Do Owners in a Consumer-to-Consumer Market Ever Prefer Renting to Less-Engaged Users?

EXTENDED ABSTRACT

Understanding owners’ preferences in a secondary market place is important for consumer-to-consumer rental platforms, which depend on owners to provide a steady supply of products, as well as for users, who often compete with other users to rent an item. For example, highly-engaged users may communicate their enthusiasm for the product when interacting with the owner. How do such signals of high (vs. low) user engagement affect owners’ likelihood to approve a rental request?

From a theoretical perspective, the processes that might influence owners’ decisions in a rental context are not well-understood. On one hand, renting to a highly-engaged user may feel benevolent, be personally validating, and create opportunities for the product to be enjoyed rather than stored—we refer to this motivation as enjoyment maximization. On the other hand, owners may be concerned that a highly-engaged user, by using the product more frequently, will place greater wear-and-tear on the product—we refer to this motivation as wear minimization. Prior research is agnostic as to which of these motivations will dominate owners’ decisions in a rental context. Further, we predict that compared to weakly attached owners, strongly attached owners will be motivated to a greater extent by wear minimization. This prediction is based on the reasoning that for strongly attached owners, the product is imbued with emotional history that would be lost if the product were replaced. We conduct a series of three experimental studies.

Study 1 (n=359) examines whether owners prefer to rent their possessions to users who communicate low versus high levels of engagement by utilizing an experimental design in which user engagement (high vs. low) was manipulated between-participants, and product attachment was measured. Participants were instructed to imagine that they owned their primary residence and had listed it on a property rental site (i.e., Airbnb), where a potential guest had contacted them who was an author planning to write at their home (high user engagement) versus at a nearby coffee shop (low use engagement). Subsequently, we measured participants’ renter preference over three items (α = .92) that were averaged to form a composite preference rating for the potential renter. We measured participants’ attachment to their primary residence with a modified version of the Inclusion of the Other in the Self scale (Aron, Aron, and Smollan, 1992), which consists of seven Venn-like diagrams. The composite measure of participants’ preference for the potential renter was regressed on user engagement (0 = low, 1 = high), their mean-centered attachment rating, and the interaction of these variables. We observed a main effect of engagement (B = -7.29, SE = 2.30, p < .01) such that owners preferred the low-engagement user (M = 73.56, SD = 20.12, N = 181) over the high-engagement user (M = 66.33, SD = 23.86, N = 178). We detected a significant interaction between engagement and attachment (B = -3.38, SE = 1.20, p < .01).

Only among strongly attached owners, the low-engagement user was preferred over the high-engagement user.

The objective of study 2 (n=378) was to show that owners’ emotional attachment affects their relative preference for users who communicate high versus low levels of potential engagement. In a 2 (product attachment) x 3 (product category) mixed design, participants learned they recently joined a product sharing website and planned to rent out products they owned and were strongly (vs. weakly) attached to. All participants were then informed that two interested renters responded to their listing, with one renter using it more frequently than the other. Our primary dependent measure was participants’ strength of preference for one renter over the other. Participants also indicated the importance of considering differences in potential wear-and-tear and enjoyment when choosing a renter. A 2 (owner attachment) x 3 (product category) mixed ANOVA on renter preference returned a main effect of owner attachment (F(1, 376) = 5.62, p = .018, η² = .02) such that participants in the strong-attachment condition preferred the low-engagement user relatively more than participants in the weak-attachment condition. Further, planned contrasts showed that strongly attached owners were motivated by wear minimization more than weakly attached owners. Mediation
analysis (Hayes 2013) revealed a significant indirect effect of attachment on renter preference through wear minimization ($B = -3.61$, SE = 1.42, 95% confidence interval [CI] = -6.47, -0.88) but not through enjoyment maximization.

Study 3 ($n=239$) examines whether financial risk of damage affects the likelihood of strongly versus weakly attached owners to list their product for rent on a product sharing website that attracts high-engagement users. In a 2 (product attachment) x 2 (financial risk) between-participants design, participants were asked to think about a possession they were strongly [not at all] attached to for about $100 and imagined planning a vacation during which they were unable to use it. Only participants in the low financial risk condition read that the website offers a 100% money back guarantee. A 2 (owner attachment) x 2 (financial risk) between-participants ANOVA on listing likelihood showed a significant interaction of owner attachment and financial risk ($F(1, 235) = 5.09$, $p = .025, \eta^2_p = .02$). Weakly attached owners were more likely to list their product for rent when their financial risk was low, whereas strongly attached owners did not differ. When financial risk was low, we found a significant indirect effect of attachment on renting likelihood through wear minimization ($B = -8.08$, SE = 3.14, 95% confidence interval [CI] = -14.55, -2.51) but not through enjoyment maximization. This result is in line with our theorizing that owners often perceive cherished possessions as unique and non-replaceable.

Together, these results expand our understanding of how product attachment influences owner decisions not only when selling possessions (Brough and Isaac 2012), but also when renting them. Managerially, our results suggest that platforms may be able to encourage owners to list their products by employing tactics that mitigate financial risk, but that such attempts may be less successful among strongly (vs. weakly) attached owners.

**A Little Piece of Me: When Mortality Reminders Lead to Possession Donation**

**EXTENDED ABSTRACT**

Humans have a unique ability to think self-reflectively. As such, we are faced with awareness that death is inevitable; a notion that creates existential anxiety. Terror Management Theory (TMT; Greenberg, Solomon, and Pyszczynski 1997; Solomon, Greenberg, and Pyszczynski 1991) suggests that, when faced with their own mortality, people engage in different forms of worldview defense that help buffer against this anxiety. For example, mortality salience (MS) has been shown to increase behaviors and attitudes that support cultural worldviews and defend against views that are counter to one’s core beliefs (e.g., punishing those who disconfirm one’s values; Greenberg et al. 1990).

TMT theory suggests that upholding cultural worldviews provides a sense of symbolic immortality—that one is a valuable part of something larger, more significant, and more resilient than one’s own existence. In a capitalistic society, one cultural norm is to be materialistic. Thus, past work finds that MS increases materialistic and self-serving tendencies (Arndt et al. 2004; Kasser and Sheldon 2000; Mandel and Heine 1999; Rindfleisch, Burroughs, and Wong 2009). Therefore, one potential hypothesis is that MS should decrease willingness to give one’s own possessions to others. However, we identify a novel mechanism through which mortality salience can increase possession donation—transcendence. We hypothesize that MS increases desire for transcendence (i.e., to be a part of something bigger than the self so one might exist beyond death) which can be attained by giving away things that are connected to the self. We make this prediction by drawing on other work that suggests that possessions are a part of the extended self (Belk 1988; Price, Arnould, and Curasi 2000). Thus, MS should increase giving behavior, but only when there is the potential for transcendence (i.e., the possession is highly connected to the self).

In Study 1, using a 2 (MS v. Control) x 2 (Sign v. No Sign) between-subjects design, we explore whether MS increases actual donation of books when the self is connected to the possession, via a signature. Prior to arriving, participants were asked to bring a book they no longer use. Participants first underwent a MS manipulation and completed a filler task. They were then told that the university teamed with a local charity to do a book drive. In the sign condition, participants were told that the charity wanted them to write a small inscription and sign their name in the book. In the no sign condition, participants did not sign. Participants were asked whether they wanted to donate the book and, if so, to place the book in the donation bin. The results revealed that those under MS who signed the book were more likely to donate (51.3%) than the control condition (39.2%; $Z = 1.90, p = .05$). In addition, the MS condition were more likely to donate the book when they signed (51.3%) versus didn’t sign (34.5%; $Z = 2.70, p = .007$).

In Study 2, we tested whether desire for transcendence motivated donation under mortality salience by asking people to choose between donating in ways that connected the self to the possession (via an inscription) or not. We found that participants in the MS were more likely to choose donating with a personal inscription (60.2%) than the control (39.8%; $Z = 2.03$, $p = .04$; $\chi^2 = 4.12$, $p = .042$).

In Study 3, we replicate the effects of donation intention from S1 using a different form of self-connected possessions. Using a 2 (MS v. Control) x 2 (Self-Connected v. Non-Self-Connected Possession) between-subjects design. Participants were asked to think about a self-connected or non-self-connected owned possession then randomly assigned to write about a MS or control experience. Finally, participants were asked their intentions to donate possession to a charity. Results revealed a significant interaction ($F(1, 434) = 4.18$, $p = .04$) such that when the possession was self-connected, MS led to greater donation intention ($M = 3.03$) than control condition ($M = 2.46$, $t(434) = 2.42$, $p = .02$). This study also found that participants under MS who thought about a self-connected possession and donated the item felt higher perceived transcendence.

Study 4, we examine whether the effects are eliminated when the desire for transcendence has already been satiated. This study utilized a 2 (MS v. Control) x 2 (Transcendent Group v. Non-Transcendent Group) between-subjects design. Participants were given a MS manipulation then told that they just joined a group that would either disappear once they were gone (non-transcendent group) or live on after them (transcendent group; Routledge and Arndt 2008). Finally, participants were asked how likely they would be to give a self-connected possession. Results revealed a significant interaction of experience and immortality ($F (1, 375) = 3.98$, $p = .047$). While the basic effect replicated in the non-transcendent group condition ($MS M = 5.92$, Control $M = 5.38$, $t(375) = 2.11$, $p = .036$), donation likelihood under MS decreased when participants had other means of transcendence ($M_{transcendent} = 5.37$, $M_{non-transcendent} = 5.92$, $t(375) = 2.15$, $p = .032$).

Finally, Study 5 demonstrated that the observed effects are mitigated when the donated items no longer allowed for transcendence (i.e., the possession would be broken down and recycled, rather than passed along to another person). Results revealed a significant interaction of experience and donation type ($F(1, 393) = 3.96$, $p = .047$) such that MS led to higher donation intention when the item was donated intact ($M = 4.94$) than recycled ($M = 3.18$, $t(393) = 5.84$, $p < .001$).
Taken together, this work provides evidence that transcendence is a novel mechanism through which MS results in increased possession donation. In contrast to past work that shows when MS will lead to selfish and materialistic behaviors, we show that MS increases giving when possessions are imbued with a sense of self. Counterintuitively, we find that MS prompts people to be more likely to give away items that are highly connected to the self because this is the condition under which self-transcendence is highest.

**Identities Without Products: Can Choice about Self-Linked Possessions be Attachment-Free?**

**EXTENDED ABSTRACT**

Previous research assumes that the strength of attachment consumers feel to an owned product always affects their decisions about that product. In contrast, we ask whether a strong possession-self link is sometimes not a determining factor in consumer choice. To address this question, we introduce a theoretical distinction between product-dependent and product-independent identities and test the impact of these identities on consumer choice. An identity is product-dependent if enacting that identity requires using particular tools or equipment. For example, enacting the identity of “cook” requires using specialized knives, rendering this identity product-dependent. Conversely, enacting the identity of “foodie” only requires using one’s senses (e.g., one’s taste to appreciate food), rendering this identity product-independent.

Building on the extant research on the dynamic use of various identity markers in delineating the boundaries of the self (Ferraro, Escalas, and Bettman 2011; Weiss and Johar 2013), we suggest that when the situationally active identity is product-independent, people will expect objects in general to be ineffective as identity markers. When people see their identities as less reliant on objects, they will be less likely to mentally symbolize objects in terms of the self, as “me” or “not-me,” rendering these people less mindful of how strongly any possession is self-linked. Consequently, the strength of the possession-self link will have low (or even no) effect on consumer choice when the situationally active identity is product-independent.

We test this prediction in the context of the consumer choice between using a possession and using an unowned product, such as a rented version of this product. We predict that the expected preference of people with strong possession-self links for using their own possessions (vs. using unowned rentals; Bardhi and Eckhardt 2017) will weaken when a product-independent identity is situationally active. Priming product-independent identities will therefore increase the tendency to rent by people with strong possession-self links without weakening the strength of these links.

**Methodology overview.** In all the studies, we first manipulate the activated identity by having participants read the definition of either a product-independent or a product-dependent identity and then reflect on its personal relevance. Participants then choose between paying to participate in an upcoming activity using their own equipment and paying more to participate using better rentals.

Study 1 used 309 students. The primed identity was musicophile (product-independent) or audiophile (product-dependent). After participants were informed about an upcoming silent concert (where the audience listens to music via headphones), they then made an incentive-compatible choice between (i) paying to use a radio connector that will allow them to use their own headphones and (ii) paying more to rent the event’s wireless headphones that have better sound. Participants’ self-link to their headphones was then measured (it was unaffected by the identity manipulation; \( p = .45 \)). A logistic regression showed that priming a product-independent identity increased renting (\( \beta = .67, p < .02 \)). The interaction with self-link strength was also significant (\( \beta = 1.17, p = .0002 \)). Consistent with predictions, priming a product-independent identity reduced consumers’ reliance on the strength of their headphones-self links: stronger self-links predicted [did not predict] less renting when the primed identity was audiophile (\( \beta = -1.04, p = .0001 \)) [musicophile (\( \beta = .13, p > .4 \))]. Also consistent with predictions, the likelihood to use rented (vs. owned) headphones was significantly higher for the musicophile (vs. audiophile) condition mainly when the headphones-self link was strong (.128 SDs below the mean or higher).

Study 2 used 279 students. It incorporated two key changes: (i) the primed identities of outdoor enthusiast (product-dependent) vs. nature enthusiast (product-independent) were irrelevant to the product (headphones); (ii) a control condition with no identity prime was added. The incentive-compatible choice mirrored Study 1’s results: Stronger headphones-self links (unaffected by the identity manipulation; \( p = .52 \)) predicted less renting in the product-dependent (\( \beta = -.75, p = .01 \)) and control (\( \beta = -.48, p = .03 \)) conditions, but did not predict less renting in the product-independent condition (\( \beta = .25, p > .22 \)). The likelihood to use rented (vs. owned) headphones was significantly higher for the nature-enthusiast (vs. outdoor-enthusiast [control]) condition mainly when the possession-self link to the headphones was strong (.063 SDs below .69 SDs above) the mean or higher).

Study 3 used Study 2’s (product-irrelevant) identities with 308 M-Turk workers. Instead of measuring the possession-self link strength, we pre-screened participants to include only those for whom we had ex-ante expectations about whether they would feel strong or weak self-links to headphones they imagined owning. Based on prior research (Morewedge et al. 2009) and pretesting, real-life ownership of headphones served as this indicator (own = strong self-link, not own = weak self-link). The renting choice mirrored results of the other studies. Strong (vs. weak) headphones-self links (based on the real-life ownership indicator) predicted less renting in the product-dependent condition (29% [24/82 participants] vs. 51% [38/75 participants], \( p = .006 \)), but did not predict less renting in the product-independent condition (49% [37/75 participants] vs. 38% [29/76 participants], \( p > .16 \)). Moreover, the likelihood to use rented (vs. owned) headphones was significantly higher for the nature (vs. outdoor) enthusiast condition only for participants with strong headphones-self links (49% [37/75 participants] vs. 29% [24/82 participants], \( p = .01 \)), and not for participants with weak headphones-self links (38% or 29/76 vs. 51% or 38/75, \( p > .12 \)). Finally, the effect of identity on renting was statistically mediated by participants’ reliance on the strength of their self-links to products (measured after the renting choice using an established measure; Weiss and Johar 2013).

Study 4 used Studies 2 and 3’s (product-irrelevant) identities with 221 M-Turk workers. It demonstrated the generalizability of the findings by replicating the results pattern in a different context (cooking master class) and product category (kitchen knives). Real-life ownership over kitchen knives served as an indicator for participants’ strong self-links to the knives they imagined owning (as in Study 3). We discuss the implications of our findings for research on possession-self links and consumer identity and for the marketing of rental services.

SESSION OVERVIEW
Complexity is like obscenity: people know it when they see it. However, the seemingly intuitive nature of the construct of complexity has meant that consumer behavior researchers have devoted little attention to it. Though it has not been a hot topic, complexity’s correlates are a who’s who of phenomena that matter in decision making: perceived understanding, attention, motivation, effort, extremity of evaluations, and probability judgments, for example.

The proposed session explores two broad research questions:
1. What exactly does complexity mean? When consumers or researchers say something is complex, what are they describing?
2. What are the downstream marketing consequences of consumers encountering subjective and objective complexity in their environments?

The goal of our proposed session is to bring together previously disparate findings from work on branding, pricing, information processing, mental representation, and computer science in order to shed new light on how complexity affects consumer behavior. In presenting these four papers, we hope to begin to form a partial understanding of the construct, its antecedents and consequences, in a more systematic way than has been done in the past.

In the first paper, the authors explore what aspects of company marketing influence consumers’ perceptions of simplicity/complexity of companies in general. They then test the downstream consequences of these perceptions on consumer beliefs about the risk of product or service failures.

In the second paper, the authors take a different approach to exploring how a type of complexity affects perceptions of brands. They examine whether consumers’ representations of brands include beliefs about how features of those brands are causally related. They find that changes to features that are seen as linked to many other features of the brand are viewed as more disruptive to the consistency of a brand’s identity.

In the third paper, the authors study the effects of complexity in the domain of consumer financial decision making. They find that consumers actually prefer more complex fee disclosures because they believe it signals transparency and facilitates decision-making. However, that same complexity can increase the likelihood of consumers choosing higher-fee options.

In the final paper, the authors demonstrate a mechanism for how consumers make judgments of similarity within sets of stimuli or products. They argue that groups of objects exhibiting some regularity in their differences (low complexity) are judged to be more similar than groups that do not, and show that consumers like product line extensions that are perceived to create more similar sets (i.e. sets of low complexity) than those that create less similar sets.

With this session, we hope to bring the topic of complexity squarely into the field of consumer research. We believe the session fits well with this year’s conference theme, “Becoming Wise,” because of the negative correlations of complexity and information density with feelings of knowledge and overconfidence, several of which will be discussed. The proposed session will appeal to researchers interested in judgement and decision making, mental representation, branding, and financial decision making.

Keep It Simple (Sometimes): Consumer Perceptions of Brand Simplicity and Risk

EXTENDED ABSTRACT
Many marketers believe that the current magnitude of marketing activity causes information overload among consumers (Spender & Freeman, 2012). As a result, simplicity of branding has emerged as a widespread strategy for attempting to reach consumers through the clutter (Alto, 2015; Siegel+Gale, 2017). At the same time, when they are overloaded with information, consumers are more likely to use decision making heuristics (Bettman, Luce, & Payne, 1998; Mahotra, 1984). We argue that one such heuristic exists and may cause unintended consequences of simple branding.

This work contributes to the literatures on branding, risk, and mental representation by examining a previously unexplored phenomenon whereby consumers feel that other aspects of a company should be simple due to perceived simplicity of branding. Across two studies, we show that: (1) consumers use branding simplicity as a cue to the simplicity of companies themselves; (2) this leads to decreased perceptions of risk for “simpler” brands; (3) which causes more dissatisfaction with eventual product or service failures (vs. “complex” brands).

Although empirical validation of a brand simplicity scale is beyond the scope of this project, the construct of brand simplicity is novel, and there is little related work in the marketing literature. Therefore, we conducted study 1 in an effort to better understand the antecedents of consumer perceptions of brand simplicity that could be subsequently used in an experimental study. Two-hundred sixty-six Amazon Mechanical Turk participants were recruited through TurkPrime (Litman, Robinson, & Abberbock, 2017)Mechanical Turk (MTurk). The survey contained 40 brand-conditions, and each participant was randomly assigned to only one brand-condition per session. The 40 brands in the survey included five brands each in eight different product categories: cars, mattresses, athletic shoes, mobile phones, financial services, insurance, hair products, and headphones.

We used structural equation modeling to empirically examine how consumer perceptions of branding elements and business pro-
cesses form latent constructs that contribute to consumers' overall perceptions of brand simplicity. We began with a theoretically-derived structural regression model which we subsequently refined.

We hypothesized the existence of three latent factors that contribute to consumers' overall perception of simplicity of a company: a visual/tangible factor, a process/understanding factor, and a dimensionality factor. We also hypothesized the existence of a fourth, "dependent" factor, which captures consumers' perceptions of the overall simplicity of a brand.

Initial model modification indices suggested removing the dimensionality factor, and the refined model was analyzed in Mplus version 8 (Muthén & Muthén, 2017). Output indicated a good fit for the hypothesized model, \( \chi^2 (98) = 363.39, p = .00, \) \( \text{CFI} = .963, \text{TLI} = .955. \) More interestingly for the study’s goals, however, the standardized coefficient for the effect of the Visual/Tangible factor on the overall Simplicity factor was \( .61 (p = .00), \) and that of the Process/Understanding factor was \( .20 (p = .18). \) The standardized estimate of residual variance in the overall Simplicity factor was \( .47, \) indicating that the two predictor latent factors explained approximately 53% of its variance. No further model modifications were made. Based on the data, visual elements of branding appear to have a greater effect on consumers’ overall perceptions of brand simplicity than perceptions of the simplicity/complexity—or understanding—of business processes.

Study 2 tested the hypothesis that consumers perceive less risk among brand products perceived to be simpler. 170 Amazon Mechanical Turk participants evaluated eight companies from four product categories (insurance, cars, headphones, and financial services). Participants evaluates the websites and ads from eight of the 40 brands in study 1. Participants answered randomly-ordered, questions measuring perceived overall simplicity/complexity of the brands, liking of the brands, and predicted risk of encountering unexpected problems with companies' products/services, as well as demographic measures. A linear mixed-effects model allowing for random effects for brand revealed the hypothesized effect of complexity on risk (\( B_{\text{complexity}} = .32, \tau(182.9) = 8.75, p < .001 \)). Over and above the effects of liking, consumers believe that simpler brands carry less risk than complex brands.

Study 3 was designed to provide further support for the causal effect of complexity on risk perceptions by manipulating complexity of branding in a within-subjects experiment. 617 Amazon Mechanical Turk participants were randomly assigned to evaluate two companies' marketing images from the same product category from five possible product categories (apparel, bikes, software, food services, and financial services). For their assigned product category, participants saw one simple and one complex marketing image, all of which were created by the experimenters (presentation order: simple or complex company first, was counterbalanced). For each company/image, participants answered questions about the perceived size of the company, professionalism, degree of luxury, and how much they liked the company. Lasty, participants were shown the marketing images again (order counterbalanced) and were asked to rate whether consumers from the simple or complex company (presented as Company A and Company B) were more likely to experience unexpected issues.

The complexity manipulation was successful: the average within-subject perceived difference in complexity between the complex and simple stimuli across the five product categories was 2.18 on an eight-point scale (\( \tau(616) = 27.88, p < .0001 \)). We used a linear mixed-effects model with random effects for category, four difference score control variables (complex minus simple) for perceived size, luxury, professionalism, and liking, as well as a contrast-coded presentation order control variable, to test the effect of manipulated complexity on perceived risk of unexpected issues. Because the dependent measure in the experiment was a single bimodal measure with one company at one end and the other company at the other, we centered the dependent variable at the midpoint of the scale. This allows us to easily interpret and test the intercept of the model, with positive intercept values indicating perceptions of more risk for the more complex company, and negative indicating more risk for the simple company. As hypothesized, the model results show that consumers believe that more complex brands carry more risk than simple brands, over and above the effects of perceived differences in liking, luxury, professionalism, and size (\( b_{\text{intercept}} = .21, \tau(608) = 3.09, p = .002). \)

**Using Consumers’ Representation of Brands to Understand Which Changes Disrupt Identity**

**EXTENDED ABSTRACT**

Brands serve a variety of important functions for consumers. Brands are the basis for inferences that drive product use (Loken 2006) and are relationship partners (Aaker 2004). These functions are contingent on the brand keeping its identity—if consumers perceive that the brand has changed in ways that make it seem like a different brand, the relationships and inferences that the brand supported may be undermined. As brands must change in response to the evolving market, a major challenge is understanding which changes will disrupt the identity of a brand and negatively affect its relationship with its consumers and which changes will not.

The current research aims to answer these questions by exploring how consumers mentally represent brands. Building on research that suggests that the representation of consumers’ own identities critically includes complex beliefs about how the aspects of the self are causally related (Chen et al. 2016), we examine whether representations of brands include beliefs about how the features of brands are causally related. Based on previous research (Rehder and Hastie 2001), we predict that changes to aspects of the brand that are seen as *causally central* (causally linked to many other features of the brand) will be seen as more disruptive to identity and more negatively impact purchase intentions, compared to changes to aspects that are seen as *causally peripheral* (linked to fewer other features).

Studies 1a (N=93) and 1b (N=89) examined whether changes to aspects of brands that are seen as causally central would lead to greater perceived disruption of brand identity (i.e., the perception that the brand is a different brand than it was pre-change). Participants reported a brand that they were loyal to (e.g., Nike), eight features important to the brand’s identity (e.g., unique style, worn by athletes, globally known), the relationships that they believed existed between these features (e.g., Nike’s unique style led to it becoming globally known), and to what extent a change to each feature would make them feel as if Nike had become a different brand. As predicted, changes to more causally central features were seen as more disruptive of brand identity (Study 1a: \( M_{\text{change}} = -1.4, \tau(92) = 2.78, p < .01; \) Study 1b: \( M_{\text{change}} = .19, \tau(88) = 3.29, p < .01). \) In Study 1b, we also found that changes to more causally central features more negatively impacted (anticipated) brand loyalty (\( M_{\text{change}} = -1.7, \tau(88) = 3.49, p < .01). \) Further, perceived disruption to identity mediated the relationship between causal centrality and anticipated change to brand loyalty (mean indirect effect was significantly less than 0, \( M = .081, \tau(88) = 2.554, p = .012). \)

In Study 2 (N=60), we manipulated the same feature of the brand to be either causally central or causally peripheral. Participants read brand history scenarios of a brand that they were fond of (e.g., your favorite restaurant chain) that characterized how the
salient characteristics of the brand fit together. For example, one scenario described a restaurant chain with the following key features: 1) strong relationships with charities, 2) popular, 3) dedicated to sustainably-sourced food. Two versions of each scenario were developed so that the exact same feature (e.g., relationships with charities) was central for half of participants (linked to two other features, e.g., the restaurant's relationships with charities led to its use of sustainably-sourced food and its popularity) and peripheral for the other half (linked to only one other feature, e.g., dedication to sustainably-sourced food led to the relationships with charities, and popularity).

After reading about the brand’s history, participants choose which of two current versions of the brand they would rather purchase from. Each was missing one feature (e.g., no longer had the relationships or the sustainable-sourcing). According to our account, participants should be more likely to pick the brand missing the peripheral feature than the central feature. Consistent with the hypothesis, participants were significantly more likely than chance to pick the brand missing the peripheral feature over the brand missing the central feature (65%, binomial sign test, p < .01). Thus, the exact same feature was perceived as being more or less important to identity depending on its causal relationships. Additionally, participants rated changes to the causally central features as transforming the brand into more of a different brand than changes to causally central features (M_central = 62.07, M_peripheral = 45.77, t(59) = 3.25, p < .01). Thus, the exact same feature was perceived as being more or less important to identity depending on its causal relationships. Additionally, participants rated changes to the causally central features as transforming the brand into more of a different brand than changes to causally central features (M_central = 62.07, M_peripheral = 45.77, t(59) = 3.25, p < .01).

Further, perceptions that the brand had transformed into a different brand predicted participants’ choice of brand. Participants were more likely to choose the brand that was missing the causally peripheral feature to the extent that they perceived that a change to the causally central feature changed brand identity more than a change to a causally peripheral feature (Wald = 20.82, p < .001).

In Study 3 (N=60), we replicated Study 2 with a type of serial brand (a brand that consumers expect ongoing changes to), sports teams. Participants preferred to buy a ticket to see the team that had a change to a peripheral feature (61.5%) than to see one that had a change to a central feature (38.5%, binomial sign test, p < .05). Additionally, participants rated changes to causally central features as changing brand identity more than changes to causally peripheral features (M_central = 52.15 M_peripheral = 38.79, t(59) = 2.88, p < .01). Finally, participants were again more likely to choose the team that was missing the causally peripheral feature to the extent that they perceived that a change to a causally central feature disrupted team identity more than a change to the peripheral feature (Wald = 5.63, p < .01).

In four studies, using both measure and manipulated causal centrality, we found that beliefs about the causal relationships between the features of a brand guide judgements about brand identity and brand use. Thus, communicating the relationships between the features of the brand—and not just a simple list of features or associations a brand holds—may be an important brand management tool. How consumers understand the causal structure of a brand’s features helps determine which changes imperil brand loyalty.

When Shrouded Prices Seem Transparent: A Preference for Costly Complexity

EXTENDED ABSTRACT

Price is a major factor in most purchasing decisions, and firms can shroud (e.g., hide, obfuscate) costs in many ways (Gabbaï & Laißon, 2006). For example, computational complexity makes it difficult for decision-makers to identify total costs, causing people to choose dominated options (Carpenter et al., 2018), which firms can exploit by making fees more complex, rather than lowering prices (Carlin, 2008). Yet, less is known about demand for complex disclosures. Consumers prefer a type of complexity, price partitioning, in many circumstances (Abraham & Hamilton, 2018), but are these consumers’ preferences for complexity aligned with their decision-making abilities?

We propose consumers can prefer more complexity despite complexity reducing their ability to identify total fees. While a vast literature has documented both people’s desire to avoid useful information (see Golman, Hagmann, & Loewenstein, 2017) and people’s tendency to seek non-instrumental information (Bastardi & Shafir, 1998; Eliaz & Schotter, 2007, 2010; Tsai, Klayman, & Hastie, 2008), less research has identified cases where individuals prefer to have information in cases where more information handicaps their decision making.

In five studies conducted on Mechanical Turk, we displayed fee disclosures for a consumer good. For Study 1 (N = 256), Study 3a (N = 293), and Study 3b (N = 397), the consumer good was prepaid cards; for Study 2 (N = 610), the consumer good was either phone plans or prepaid cards; for Study 4 (N = 932), the consumer good was either phone plans, closing fees for purchase of a property, or wedding venues. Complexity was manipulated by unnecessarily disaggregating fees in ways that would not impact payoffs. For example, in the complex condition for prepaid cards, a category of “Initial Fees” included a “Card Acquisition Fee,” a “Card Activation Fee,” a “Service Fee,” and an “Administration Fee”; these amounts were summed and displayed simply as “Initial Fees” in the in the simple condition.

Participants first completed a preference elicitation task. We displayed one of each type of disclosure side-by-side, holding total fees constant and highlighting this fact in the instructions. Participants clicked a radio button next to their preferred disclosure. Next, participants completed the selection task. Regardless of participants’ disclosure preferences, we randomly assigned them to make an incentivized choice between two options that had the same disclosure type. For example, in Study 1, some participants chose between two prepaid cards with simple disclosures, while others chose between two prepaid cards with complex disclosures. We incentivized selection of lower-fee options with a bonus payment.

Across all studies and conditions, a majority of participants preferred complex to simple disclosures (Study 1: 70%; Study 2: 70%; Study 3a: 61%; Study 3b: 63%; Study 4: 55%). Additionally, participants in complex conditions were more likely to select higher-fee (financially dominated) options (all χ²(1)s > 8.42, all ps < .005). In all studies, disclosure preferences were not significantly related to selecting the higher-fee card in the selection task, neither overall nor differentially across conditions (all χ²(1)s < 1.10, all ps > .296). Hence, participants on average preferred complexity that increased their likelihood of selecting dominated options.

After Study 1, which confirmed our primary hypotheses, we sought to identify whether people change their preferences after experience with the task of selecting lower-price options. Study 2 elicited preferences a second time after the selection task. Preferences did not significantly change from the first elicitation to the second elicitation (71% vs. 69% preferring the complex disclosure; χ²(1) = 47, p = .494).

To identify causal relationships between beliefs about disclosures and preferences for the complex disclosure, we tested warning messages in Studies 3a and 3b. In Study 3a, we found that warning participants that complexity leads to mistakes moderately decreased preferences for the complex display (M_no_warning = 69%, M_warning = 55%; χ²(1) = 16.36, p < .001), an effect mediated by a decrease in participants’ belief that more detailed disclosures enabled selection of lower-fee options relative to simple disclosures (M_no_warning = 1.57;
In Study 3b, we found that an “obfuscation” warning, which warned that companies can increase complexity to obfuscate fees, decreased a preference for the complex disclosure with marginal significance ($M_{\text{complex}}=.70\%$, $M_{\text{simple}}=.95\%$; obfuscation vs. control: $p = .088$), an effect mediated by a decrease in the perceived transparency and trustworthiness of the complex disclosure relative to the simple disclosure ($M_{\text{transparency}}=2.67$, $M_{\text{trustworthiness}}=3.47$, $p=.021$; bootstrapped average proportion mediated=.63, $p=.016$). Yet, we note that in Studies 3a and 3b, a majority of participants who viewed warnings still preferred the complex disclosure, believed on average that the complex disclosure enabled decision making more than the simple disclosure, and believed that the complex disclosures signaled transparency and trustworthiness more than the simple disclosure.

In Study 4, we tested a third type of disclosure commonly found in the real world: a complex disclosure with “summary information” making total fees easier to identify. The “summary information” condition included both disaggregated fees and total fees. When participants ranked each disclosure type, the summary information disclosure was preferred by most participants (71%), though participants again ranked the complex disclosure as more preferable than the simple disclosure (55%). Furthermore, participants assigned to the summary information condition in the selection task performed very similarly to participants assigned to the simple condition, and both of these groups performed better than participants assigned to the complex condition (all scenarios combined, $DV=\text{selection of low-cost option}$: $M_{\text{simple}}=.19$, $M_{\text{complex}}=.30$, $M_{\text{summary}}=.20$; complex v. simple: $p=.002$; complex v. summary information: $p=.006$; simple v. summary information: $p = .801$). Hence, the summary information disclosure both enabled selection of lower-cost options (relative to the complex disclosure) and was the most preferred.

We show that individuals can prefer complexity that costs them, believing the detail of complex disclosures to enable their decision making when it can actually do the opposite, allowing firms to shroud prices while appearing transparent. Furthermore, a comparison of interventions across studies suggests that policy solutions aiming to work with, or channel, consumer preferences could be more effective than informational campaigns to change consumer preferences.

## Low Complexity Drives Similarity Judgments within Sets of Stimuli

**EXTEDNED ABSTRACT**

Many day-to-day decisions require some sort of similarity judgment. For example, similarity judgments have found to affect decision time in choice (Bhatia & Mullett, 2018), preference between target and competitor products (Huber et. al, 1982), and line- and brand-extensions (Desai & Hoyer, 1993). Understanding the fundamental underpinnings of similarity judgments will therefore help us understand decisions in a variety of domains. Although many theories of similarity exist in the literature, we focus on two prevalent theories proposed by Tversky (1977) and Hahn et al (2003).

Tversky (1977) theorized similarity as a function of feature-matching process. People weight the shared and distinct features of the two objects and combine these two into an overall similarity judgment. In this model, an increase in shared features and a decrease in distinct features both result in higher similarity scores.

Hahn et al (2003) theorized similarity as a function of representational distortions (transformations); increase in number of transformations would decrease similarity judgment. For example, (A) red triangle vs. blue triangle and (B) red triangle vs. blue square, (A) only has one transformation (color) while (B) has two (color and shape). Under Hahn and colleagues’ account, (A) would be judged more similar than (B) due to fewer distortions.

Despite the prevalence of these two theories, both are limited to similarity judgments between two individual stimuli. The current research investigates how people judge the similarity between two or more objects and finds that groups of objects exhibiting some regularity in their differences are judged to be more similar than groups that do not. For example, participants believe a set comprising of “2,4,6,8,10” to be more similar than “2,4,8,8,10” even though the latter would be predicted to be judged more similarly under reasonable extensions of both Tversky’s and Hahn’s models.

More specifically, we conducted three studies to investigate how regularity in differences affects judgments of similarity, and two additional studies to test the downstream consequences on the evaluation of line-extensions.

We hypothesized that regularity in differences increase judgment of similarity when judging a group of objects that are all different in features. Our hypotheses are based on the concept of Kolmogorov complexity; which quantifies complexity as the length of the shortest computer program that can generate the representation. For example; under Kolmogorov complexity, a string composed of a million 1’s will be classified as less complex than a thousand random alphabet characters since the former can be reduced to a shorter program. Effects of Kolmogorov complexity have been documented in the domain of liking and preferences (Evers et al, 2014) and sense-making (Chater & Lowenstein, 2016). Based on this research, we expected that Kolmogorov complexity could also play a role in similarity judgments.

In Studies 1-3 we tested the basic effect using a variety of abstract stimuli and products. For example, for Study 1 we used 56 strings of numbers, where each string was categorized into one of five conditions: (1) All same (e.g., “4,4,4,4,4”), (2) Equal intervals (e.g., “1,3,5,7,9”), (3) Two-same three-different (e.g., “2,6,0,8,8”), (4) Unequal intervals (e.g., “3,8,2,9,7”), and (5) Monotonic unequal intervals (e.g., “0,1,3,6,9”). We then asked participants to judge the similarity of all 56 strings. We expected the lowest ratings of similarity for the all-different strings without any regularity (Condition 4 and 5), and highest similarity judgments for the all equal strings (consistent with Tversky and Hahn et al). Crucially, however, we expected a higher judgment of similarity for the strings exhibiting low complexity (regular differences) compared to the other conditions, even the condition in which the strings included identical numbers. As hypothesized, our results showed that items in the low complexity condition were judged to be much more similar than the other conditions (In Study 1: $M = 54.99$ vs. $47.78$, $29.87$, $34.71$; respectively, $ps < .001$). Study 2 served as pre-registered replications of Study 1 with an additional sixth condition, and using different stimuli (shapes) that allowed us to quantify exactly how low-complexity affects similarity judgments. Our results replicated those of Study 1 (all important p-values < .001).

In Study 3, we move from abstract stimuli to products to test whether we find the same effects when participants are asked to evaluate bundles of consumer goods. Consistent with studies 1 and 2, we find that when consumers evaluate assortments of sneakers, assortments that are low in complexity are evaluated to be more similar ($M = 60.11$, $SD = 23.63$) than assortments that do not (even if there is more objective overlap in features; $M = 52.77$, $SD = 25.55$, $Z = 4.82$, $p < .001$).

In Studies 4 and 5 we extend these findings to evaluations of line-extensions. In Study 4, we present participants with an assortment of sneakers, and ask them to evaluate new additions to the as-
sortment. These new additions either “fit” with the initial structure of the assortment (therefore keeping complexity low), or did not. We expected that, because products in low-complexity sets are perceived to be more similar to each other, participants would therefore hold more positive attitudes to these line-extensions. Consistent with the results of Study 3, target shoes were perceived to be a better fit when their addition would keep complexity low \((M = 64.05, SD = 23.48)\) as compared to situations in which they increased the complexity \((M = 57.07, SD = 25.70, Z = 4.26, p < .001)\). Study 5 replicates these findings using different flavors of beer, and having participants evaluate novel line-extensions.

To summarize, in 5 studies we find that the complexity of assortments affects both judgments of similarity, as well as evaluations of line-extensions. More specifically, the lower the complexity of the assortment, the more similar products in this assortment are perceived to be. Additionally, novel items that keep the complexity of the assortment low are perceived to be better line-extensions.

REFERENCES
SESSION OVERVIEW

New technology generates new possibilities, but also new concerns. For example, developments in data-driven marketing practices have generated consumer concern over privacy (e.g., a recent data breach of over 50 million accounts on Facebook) or concern over diminishing sense of autonomy (Andre et al. 2017). How can the field of consumer research contribute to designing better technology practices? Developing a good practice of technology requires consideration of both managerial and consumer welfare implications. This session brings together four papers that examine consumer responses to new technology that have substantial managerial implications and consumer welfare implications. Consistent with the conference theme of “Becoming Wise,” this session aims to create new wisdom by documenting the problems emerging with practices of new technology in the marketplace and by using insights from consumer research to solve these problems.

The first two papers derive novel insights from theories to alleviate consumer concerns over current technology practices. Madan & Savani set the stage by examining the consumer response to privacy breaches (e.g., Facebook) and by clarifying the psychological process that might help these organizations continue their relationship with its customers. They show that consumers high in power distance belief are less likely to blame organizations for the loss of privacy and prefer to resolve the privacy breaches by delegating control of their private information to the organizations (e.g., willing to pay a fee to Facebook to not sell their data to advertisers). Ding & Kyung uncover a novel intervention to reduce consumer stress from waiting time online: the moving animation. Drawing from sensation-seeking theory and visual perception, they suggest that firms could use moderately fast moving animations to reduce perceived waiting time and to enhance engagement with subsequent tasks.

The last two papers focus on the emerging practice of data-driven product recommendations. They suggest that future practices of this technology should focus on enhancing consumer trust in the recommender system while preserving consumer autonomy. Gai & Klesse focuses on consumer distrust in data-driven product recommendations and examines the potential role of recommendation explanations in increasing trust. Their findings suggest that firms should use explanations that emphasize the recommender system is recognizing the consumer’s subjective taste. Yet, Lee & Johar suggest that these technology practices that facilitate the adoption of personalized recommendations might be detrimental to consumer well-being. They show that using personalized recommendations might reduce preference clarity—a sense that one holds clearly defined, internally consistent, and stable preferences—which might undermine self-efficacy with decision making.

The present findings in this session complement and advance our understanding of consumer response to new technology. These insights encourage the field of consumer research to take the lead in designing better practices of new technology, as technological advances are rapidly transforming consumer behavior. This topic will benefit from a lively discussion on the implications of technology (mal)practices on consumer well-being and on business opportunities.

(No) Privacy Please: Power Distance Beliefs and Response to Privacy Breaches

EXTENDED ABSTRACT

In this era of ubiquitous technology, data breaches are a common occurrence. Over 600 privacy breaches, affecting over 1.5 billion consumers, were discovered in 2018 alone (Axel 2018; Leskin 2018). Not surprisingly, in a recent survey, over 90% consumers said they were very concerned about internet privacy (BlueFountain Media 2018). However, these concerns do not seem to translate into actions (Barker 2018). After a recent data breach of over 50 million accounts on Facebook, over 60% people said they would continue using Facebook (Zantal-Weiner 2018). What predicts consumers’ responses to such privacy breaches?

We posit that consumers can respond to privacy issues in one of two ways, i) take control of their privacy and ii) relinquish control to the organization. In the context of Facebook, taking control of one’s privacy encompasses behaviors like reviewing privacy settings, deleting private information, and reduced use of Facebook. On the other hand, relinquishing control translates into behaviors such as continuing to use Facebook and perhaps even supporting Facebook by paying a fee to not sell consumer data to advertisers. We argue that if consumers make depends on the extent to which they hold the organization (e.g., Facebook) responsible for the privacy breach. This in turn is driven by the degree to which consumers accept that the organization is at a higher level in the society — or that power is distributed unequally resulting in hierarchies (Power Distance Beliefs; Hofstede 2001; Zhang, Winterich, and Mittal 2010). We posit that people high in power distance may perceive organizations such as Google and Facebook to be high in power and trust their authority, therefore being less likely to blame them for the loss of privacy and further, be less likely to challenge their authority in handling these issues. However, those low in power distance will hold firms accountable for their loss of privacy and hence, be more likely to take charge of safeguarding their own privacy.

Study 1 was designed to provide initial support for the idea that consumers high in power distance will be less likely to blame Facebook for privacy breaches. 103 US residents on Amazon MTurk completed the study. Participants were randomly assigned to the high (vs. low) power distance condition. We manipulated power distance beliefs using the sentence unscrambling task by Zhang et al. (2010).
Specifically, participants were asked to unscramble ten sentences in each condition. For example, high power distance condition emphasized the importance of hierarchy with sentences such as “Hierarchy is necessary for social order”. On the other hand, the low power distance condition used sentences such as “Hierarchy is unnecessary for social order” to emphasize equality. After completing the sentence unscrambling task, participants were presented with a detailed scenario explaining that they were one of the 87 million Facebook users whose personal data was shared with Cambridge Analytica, which used their personal information to target them with political advertisements. We then asked participants to respond to two questions (“To what extent do you think Facebook is responsible for this privacy breach” and “To what extent do you blame Facebook for this loss of privacy?”). A t-test revealed that participants in the high power distance condition (M_{HighPDB}=5.49) were less likely to blame Facebook and to hold Facebook responsible for the loss of privacy than those in the low power distance condition (M_{LowPDB}=6.16, t(101)=2.3, p=.024).

The second study was designed to accomplish two objectives. First, we wanted to understand if the extent of blame and responsibility assigned to Facebook for the privacy breach would lead to different downstream behaviors. Second, we wanted to control for other potential confounding variables, such as interdependence. One hundred US residents on MTurk completed the study. Participants first responded to the 5-item power distance beliefs scale (Singelis 1994). They then read the same scenario as in Study 1 and proceeded to answer several related questions. Specifically, we asked the participants i) how likely they were to review their privacy settings on Facebook, ii) how likely they were to delete highly personal information from Facebook and iii) how likely were they to pay a small sum of money for Facebook to not sell their data to advertisers (1=not at all likely to 7=extremely likely). As theorized earlier, we expected participants low on power distance beliefs to take control of their own privacy (i.e., review privacy settings, delete personal information) and participants high in power distance to trust Facebook in resolving the privacy issue by paying Facebook to not sell their data to advertisers. Participants also responded to the two items from Study 1 measuring the extent of blame and responsibility attributed to Facebook, and the 12-item interdependence scale (Singelis 1994). Regression analysis showed that higher power distance beliefs predicted lower likelihood of taking steps to safeguard one’s privacy (β=-.23, t(107)=-2.17, p=.039) — i.e., lower likelihood of reviewing privacy settings and deleting highly personal information. However, as expected, high power distance beliefs were positively related to willingness to pay Facebook to not sell their data to advertisers (β=.43, t(107)=4.03, p<.001). The effects held even after controlling for interdependence. Finally, we tested the underlying mechanism of extent of responsibility / blame attributed to Facebook for the privacy breach. Mediation analysis using power distance score as the predictor, likelihood of reviewing privacy settings and deleting personal information as the outcome, and extent of blame / responsibility as the mediator in PROCESS Model 4 (Hayes 2017) revealed a significant indirect effect such that low power distance consumers were more likely to attribute responsibility to Facebook for the data breach and thus, more likely to take concrete steps to safeguard their own privacy (B=-.20, SE=.072, 95% CI [-.35, -.07]).

This research contributes to the nascent literature on power distance beliefs as an important construct predicting meaningful differences in consumer behavior. Further, we contribute to limited research on understanding increasingly rampant privacy issues in an interconnected world. Finally, this research has interesting implications for tech marketers for power distance based privacy management strategies.

Time Flies... But Only When the Speed is “Just Right”: How Animation Speed Affects Perceived Waiting Time

EXTENDED ABSTRACT

With more online consumption behaviors moving from computer to mobile, waiting and churning on a webpage become more concerned by marketers. For instance, 73.1% desktop users abandon shopping carts, and mobile users 85.6%. Among the users abandon their carts, 26% indicated the reason being the checkout process too long (Baymard Institute 2018).

Waiting online is torture. Consumers are impatient: Web users abandon pages after even a mere two seconds of waiting time for information retrieval (Nah 2004). Yet given the limitations of technology, waiting is sometimes a necessary evil when consumers interact with technology interfaces. A critical question for managers is how to reduce the perception of waiting time that critically impacts how consumers evaluate their experience (Gorn et al. 2004, Sackett et al. 2010).

One way to try and reduce perceived waiting time is to introduce animation to decrease perceived waiting time. Research in interface design suggests that processing bars with accelerating speeds, relative to those with constant or decelerating speed, result in the shortest perceived waiting time (Harrison, Yeo, and Hudson 2010; Matthews 2011). Similarly, research in time perception suggests that time is perceived as passing more quickly if more versus fewer visual changes occur during a particular duration (Brown 1995; Hansen and Trope 2012; Allman et al. 2014). Both streams of research suggest that increasingly faster animation speeds should result in shorter perceived waiting time. However, we suggest that faster is not always better, and that animation speed can make time fly—but only when the speed is “just right.” Five experiments (with robust replications) demonstrate that relative to fast animation speeds, moderate animation speeds during waiting time result in faster subjective time perception.

In Experiment 1a (n=615), US mTurk participants were directed to wait on a webpage (for 17 seconds, unbeknownst to participants) in the middle of the survey with either a picture of a static wheel, a slow-circling wheel (500ms per movement) or fast-circling wheel (100ms per movement). Immediately afterwards, they were asked to rate their subjective waiting time on a slider from 0 (very short) to 100 (very long) and their level of engagement. The fast-circling wheel resulted in shorter perceived wait times (35.4) relative to the static wheel (43.5, p = .001), but the slow-circling wheel resulted in an even shorter perceived wait times (30.6) relative to the fast-circling wheel (p = .04). Experiments 1b-1e replicated these effects for multiple time durations (7s, 13s, 15s, 17s), different animation pictures (wheel rotating and snail moving), different scales to measure time perception (7-point and 100-point), and different participants (Mturk adults and university students). Furthermore, three replications found that animation speed had no effect on objective waiting time estimated in seconds, but significantly affected perceptions of subjective waiting time.

Experiment 2 (n=423) tested whether the effects of animation speed extend beyond time perception to task motivation. U.S. mTurk participants were asked to solve 10 arithmetic problems (e.g. 17*5=?) and under each problem participants saw a static snail picture, a slow-moving snail (400ms per movement) or a fast-moving snail (100ms per movement), and the page advanced automatically after 40 seconds. While participants in the static (3.45) and fast-mov...
ing (3.51) conditions solved the same number of problems ($p = .78$),
those in the slow-moving condition (4.06) solved more problems
than those in both the static ($p = .008$) and fast-moving ($p = .013$)
conditions. The total number of problems answered followed a simi-
lar pattern of results. These results suggest that the slow-moving ani-
mation increased people’s speed in working through the math prob-
lem, consistent with perceiving that time was moving faster in the
slow-moving animation condition. Thus animation speed can benefit
snap speed without sacrificing accuracy, suggesting a novel interven-
tion to the traditional speed-accuracy trade-off which can increase

In Experiment 3, we explicitly test the hypothesis that there is
an optimal animation speed that is “just right” by testing seven dif-
ferent speeds (static, 50ms, 100ms, 300ms, 500ms, 700ms, 900ms),
following the same procedure as Experiment 1a. As shown below,
there is a significant quadratic effect of animation speed on subjec-
tive time perception ($b = 0.61, \text{Robust SE}=0.29, t=2.10, p = .036$),
although animation speed had no linear nor quadratic effect on ob-
jective time estimates ($ps > .2$).

In Experiments 4 and 5, we tested the boundary conditions of
this effect. Similar to the procedure of Experiment 1a, we added in
another factor in Experiment 4 that we told half participants “please
wait” while the other half “please wait for about 20 seconds.” Re-
sults showed that the effect only holds when participants are not
sure about the waiting time ($b = 7.88, \text{Robust SE}=3.00, t = 2.63, p = .009$),
but not when they were informed about the waiting time ($b =
-3.30, \text{Robust SE}=2.86, t = -1.15, p = .25$), interaction $b = -10.81,
\text{Robust SE}=4.15, t = -2.61, p = .009$. In Experiment 5, using similar
procedure of Experiment 1a, we either asked participants to indi-
cate their subjective time perception right after waiting or after a
3-minute irrelevat filler task. Results showed that the effect only
holds when consumers responded immediately after the waiting ($b =
11.64, \text{Robust SE}=3.56, t = 3.27, p = .001$), but not retrospectively
($b = -0.30, \text{Robust SE}=4.20, t = -0.07, p = .94$), interaction $b =
-11.94, \text{Robust SE}=5.50, t = -2.17, p = .031$.

Together, these studies demonstrate that animation speeds can
materially influence people’s subjective time estimates. Relative to
static or fast-moving animation speeds, more moderate animation
speeds result in the lowest perceptions of waiting time (Experiment
3), higher levels of engagement (Experiment 1a) and motivation
(Experiment 2), when consumers are uncertain about the waiting
time (Experiment 4) and responded right after their waiting expe-
rience (Experiment 5). Future research can investigate factors that
influence optimal speed and the types of customer experiences that
are improved by reducing perceived waiting time in mobile or other
technology contexts.

**How Explanations for Recommender Systems Impact
Consumer Acceptance**

**EXTENDED ABSTRACT**

Consumers frequently receive personalized product recom-
mandations from companies. To improve the accuracy of these
recommendations, existing recommender systems incorporate both
user-based input (i.e., common preferences across users) and prod-
uct-based input (i.e., common attributes across products) (Amatriain
and Basilisco 2016). Such a hybrid approach provides companies with
flexibility in terms of what they want to highlight (users or products)
when explaining the basis for their recommendation to consumers.
Some companies adopt collaborative explanations, highlighting the
overlap in preferences among users (e.g., “Customers who viewed
this item also viewed”), whereas others employ content-based ex-
planations (e.g., “More in Health”) (Tintarev & Masthoff, 2011).
We investigate how the two different types of explanations —while
keeping the actual recommendation constant —impact consumer ac-
ceptance of recommendations.

Both collaborative and content-based explanations signal to
consumers that a focal product and a recommended product relate in
some way. Collaborative explanations suggest that the two are relat-
ated because they have been consumed or liked by the same group of
consumers, whereas content-based explanations indicate that the two
products are similar to each other. Thus both explanations should
increase consumers’ awareness that the basis for the recommendation
is product-matching. But only the collaborative explanations also
highlight the preferences of others who are similar to the consumer.
Therefore, relative to content-based explanations, collaborative ex-
planations prompt consumers to recognize that the recommendation
is based on taste-matching between users. We propose that whether
consumers trust or distrust this taste-matching depends on to what
extent they see others’ tastes as self-relevant. This proposition is in
line with prior work showing that people only follow others’ behavior
when they feel connected to others (Bearden and Etzel 1982; Cialdini
and Goldstein, 2004).

Study 1 tests how the two types of explanations impact per-
ceived accuracy of recommendations. We sent an online survey to
subscribers to a company that publish their original articles on social
media. We received 757 complete responses (519 females, Mean of
age = 24). Participants were randomly assigned to read either a col-
laborative (“People who like this also like”) or content-based expla-
nation (“More in [a major category of their articles]”). Both expla-
nations had been adopted by the company (for study 3, see below)
before the survey was distributed. Participants were asked to evalu-
ate the recommender system based on the explanation they read. One
of the questions taps into the perceived accuracy of the recommenda-
tion (“The recommender system can accurately predict what I like”,
1 = strongly disagree, 6 = strongly agree). Toward the end of the
survey, participants indicated how long they have subscribed to the
company (from under 3 months to over 3 years). We assume that lon-
ger subscribers would be more likely to see other users’ preferences
as self-relevant. Indeed, a linear regression shows that the length of
subscription positively predicts the perceived accuracy of the recom-
modation for people who read the collaborative explanation ($p =
.070$) but not for those who read the content-based explanation ($p =
.376; p of the interaction = .057$).

In study 2, we look at how the two types of explanations influence
the intention to click on recommended books. Participants (N =
170 from Amazon Mechanical Turk, 73 females, Mean of age = 36)
viewed four simplified Amazon webpages of books. On each page,
there was a focal book and a recommended book. Participants
were randomly assigned to read the collaborative explanation (“Custom-
ners who viewed this also viewed”) or the content-based explanation
(“Similar to this item”) for the recommendation. Participants indi-
cated whether they would click on the recommended book (1 = not
at all, 10 = definitely). Then they rated how attractive the focal books
are. Based on their ratings, we selected the most attractive focal book
for each individual for later analysis. Toward the end of the survey,
participants reported to what extent other Amazon customers can
represent their own tastes. Given our theorizing, we expect that this
factor would positively predict the effectiveness of the collaborative
explanation. This is indeed the case ($p < .001$). On the other hand,
the relationship does not hold for the content-based explanation ($p =
.207; p of the interaction = .843$).

Study 3 and 4 examine the impact of explanations on real be-
havior. Study 3 is a field experiment in collaboration with the com-
pany in study 1. Pre-selected articles were randomly assigned to be recommended with the collaborative explanation or with the content-based explanation. Numbers of reads of focal articles (which embed the recommendations) were also recorded. More reads mean that the focal article is more appealing to readers and thus makes the taste-matching as suggested by the collaborative explanation more credible. In support of this, focal reads positively predict the reads of the articles recommended with the collaborative explanation ($p < .001$) but not with the content-based explanation ($p = .275$; $p$ of the interaction $< .001$). In study 4, we let 200 undergraduate students choose a funny movie scene to watch during the break of a lab session. After they finished watching, they rated how much they liked the video by giving 1 to 5 stars and received another recommended video. Participants were randomly assigned to view the collaborative (“People who watched this also watched”) or the content-based explanation for the recommended video (“More of funny movie scenes”). Consistent with study 3, we find that the rating of the focal video positively predicts the likelihood to watch the recommended video with the collaborative explanation ($p = .002$) but not with the content-based explanation ($p = .369$; $p$ of the interaction $= .064$). Moreover, among students who did watch the recommended video ($N = 54$), those who viewed the collaborative-explanation gave higher ratings to the recommended video than those who viewed the content-based explanation ($p = .062$).

Taken together, our findings illuminate how collaborative and content-based explanations differ in their impact on consumer acceptance of product recommendations. The results also highlight the variables that managers should consider to leverage the value of explanations for recommender systems.

**Preference Unlearning: When Personalized Recommendations Reduce Preference Clarity**

**EXTENDED ABSTRACT**

Personalized product recommendations are rapidly changing consumer behavior. In 2013 already, 35% of what consumers purchase on Amazon and 75% of what they watch on Netflix came from data-driven product recommendations (MacKenzie, Meyer, & Noble 2013). While this trend opens up a new landscape of consumers delegating decisions to technology that knows their subjective preference well, the consequences of using personalized recommendations remain underexplored. We show that, while consumers believe using personalized recommendations will increase preference clarity — the sense of having a clearly defined, internally consistent, and stable preference on a certain product domain — actually using personalized recommendations undermines preference clarity (“preference unlearning effect”). We further show that consumers with higher trust in technology are more susceptible to the effect.

Several perspectives in psychology inform our prediction of why personalized recommendations might reduce preference clarity. First, research on social comparison (Festinger 1954; Moreau & Herd 2009) suggests that recognizing a recommender system that chooses well for the self might instigate an upward comparison with the system, which reduces confidence in decision making for the self. A second possibility arises from the research on learned helplessness (Abramson, Seligman, & Teasdale 1978), which propose that people confronted with their inability to influence a situation will internalize the lack of control. To the extent that personalized recommendations make choices that one should be making salient, consumers will feel greater loss of control, which will be diminish preference clarity. Finally, consumers might develop “transactive memory” (Wegner 1987; Sparrow, Liu, & Wegner 2011) with their partner, the recommender system. In this view, the perception that the recommender system memorizes and stores one’s preference may lead to a decrease in felt responsibility in remembering one’s preference.

Study 1 ($N = 102$) examined whether consumers expect that personalized product recommendations will help them clarify and develop preference. Participants read a vignette on a consumer who had been using a music service. Whether this consumer has been relying on recommendations of songs that match her taste (personalized) or on recommendations of popular songs (others) has been manipulated between-subjects. Then participants rated the clarity in music preference that this hypothetical consumer seems to have (modified from Self-Concept Clarity scale in Campbell et al. 1996; e.g., “It will be difficult for Casey to make up her mind about which music to listen to because she doesn’t really know what she wants”). It was revealed that consumers expect significantly higher preference clarity from a consumer that has been using personalized recommendations ($M_{personalized} = 4.86$) than from a consumer that has been using non-personalized recommendations ($M_{others} = 4.10, F(1,100) = 13.318, p < .001$).

Do personalized recommendations actually help consumers boost sense of preference clarity? To examine this question, Study 2 ($N = 157$) had participants listen to a series of contemporary pop songs and measured preference clarity. All participants first listened to three music clips and provided their evaluation of the clips (thumbs up, down, or neutral). Then, all participants were presented with another series of music clips. Participants were told that these clips were chosen either based on their feedback of previous songs (personalized), based on the preference of other listeners previously logged onto the service (others), or based on the random selection from the database (random). After listening to a series of these clips, participants completed the music preference clarity scale (e.g., “It is often difficult for me to make up my mind about which music to listen to because I don’t really know what I want”). The preference unlearning hypothesis was confirmed, with personalized framing producing significantly lower sense of preference clarity ($M_{personalized} = 4.13$) than the two non-personalized framings ($M_{others} = 4.58, p < .05; M_{random} = 4.63, p < .05$). Manipulation checks and confounding checks revealed that personalized framing yielded a greater perception that the service understands one’s musical taste ($M_{personalized} = 5.05$) than non-personalized framings ($M_{others} = 3.84, p < .01; M_{random} = 3.86, p < .01$) without influencing overall enjoyment with songs listened or general interest in music. The effect of recommendation framing on preference clarity was replicated with lab subjects in Study 2b ($N = 153$).

Who are more likely to fall prey of the preference unlearning effect? We expect that people with greater trust in technology will feel more comfortable delegating their decisions to technological agents and hence will perceive greater reduction in preference clarity after receiving personalized recommendations. Study 3 ($N = 218$) examined this possibility with a lab experiment. In addition to completing the music listening task and the preference clarity scale outlined in Study 2, participants rated the extent to which they trust technology in general (Parasuraman 2000). Results again revealed the main effect of recommendation framing on preference clarity ($M_{personalized} = 4.01$ was lower than $M_{others} = 4.43, p < .05$ or $M_{random} = 4.32, p = .07$). Crucially, an interaction between recommendation-framing and trust-in-technology was found, $F(2,212) = 2.10, p = .054$. Specifically, consumers with higher (+1 SD) trust-in-technology predicted significantly lower preference clarity with personalized recommendations than with non-personalized recommendations (Others: $b = .87, p < .001$; Random: $b = .51, p < .05$). However, no such differences in predicted clarity was observed among consum-
ers with lower (-1 SD) trust-in-technology (Others: \( b = .03, p = NS \); Random: \( b = -.15, p = NS \)).

Taken together, these findings suggest that, as the recommender system learns the consumers’ subjective preferences and makes choices for them, consumers feel less clear about their preferences (preference unlearning effect). The reduced preference clarity is consequential because it could lead to detrimental psychological outcomes such as low self-esteem or anxiety in decision making (Baumgardner 1990). This paper also adds to the literature on self-view confidence, which has shown that the confidence in self-related thoughts could be shaken by such experimental manipulation as writing about the self in one’s nondominant hand (Gao, Wheeler, & Shiv 2008). This paper is first to our knowledge to show that a real-world consumer experience could shake confidence in self-view.

SESSION OVERVIEW

Consumers today navigate an increasingly complex marketplace as sense-makers and meaning producers. Oftentimes they consume not the physical product, but the idea it embodies. As consumption has increasingly moved from the physical to the conceptual (Ariely and Norton 2009), purchasing a shoe, a bag, or art involves not just the acquisition of the physical product but also the acquisition of meaning, stories and expertise that make the product what it is. This session views each marketable entity through the lens of psychological essentialism (Gelman 2004; 2013; Medin and Ortony 1989) and suggests that they all have an unobservable quality or an “essence” that differentiates them. Consumers, in their attempt to derive meaning, look for cues that help them discern this underlying “essence”. Origin dates, characteristics of the creators, history and even packaging can offer cues about the underlying essence. For example, the first paper examines the “essence” of “heritage brands”. In this case, essence appears to be a function of not only the origin date (as is often assumed) but also other factors such as the continuity of the original creator’s intent to the present day and era specific associations. Central to the thesis is the notion of continuity or essence transfer to the present times – a process that has implications for value.

Essence can also be cued through communications. The second paper examines how stories or communications about the creator’s lifestyle and the creative process can lead to essence loss. Although an artist’s essence is unobservable, consumers nevertheless perceive artists to have greater essence when they are depicted as embracing solitude as opposed to seeking social connections. Solitude preserves a creator’s essence and its subsequent transfer to creative output increases perceived creative authenticity and demand for these goods. Although retention of essence might serve the company well if consumers value it, in some instances, it might be constraining. The third paper examines situations in which a heritage brand’s essence can come in the way of innovations. Given that heritage branding typically links a product’s essence to the original intent of its creators, innovations or deviations from this intent violate this original essence, and lead to a perception that the product is not true to its origins and this can decrease perceived value for consumers.

To the extent that the retention of essence is desirable, the fourth paper points to a potential mechanism by which the essence of a good can be lost. Perceptually, essence is contained and held intact through a product’s packaging. Such packaging provides a physical barrier that not only prevents contamination, but also psychologically prevents the leakage of a product’s essence. The authors show how the absence of packaging can lead to loss of essence. Collectively the four papers provide an understanding of how subtle cues inform consumers about the essence of a marketable entity and affect the perceived meaning, authenticity and value consumers derive from products.

The Role of Origins and Essence in Heritage Branding

EXTENDED ABSTRACT

What gives a heritage brand its claim to be so described? Indeed, little investigation has gone into how consumers make judgments of a brand’s heritage— that is, the role that the brand’s history has in defining the brand identity and image for the present and future (Urde, Greyser, and Balmer 2007). The current work is an attempt to understand how a heritage brand comes to be seen as such in consumers’ minds by identifying the factors that give rise to judgments of heritage, as well as the effects that heritage have on consumer valuation.

Specifically, this work posits that the structure of a heritage brand is one in which the brand origins are continuously maintained into the current day, and that the brand’s continuity over time occurs through a process known as psychological essentialism (Medin and Ortony 1989; Gelman 2003). Specifically, the current work posits that some aspect of a brand’s beginning (such as a founder’s intentions) cultivate an “essence” of the brand that persists, which in turn facilitates consumers’ perceptions of a brand’s heritage.

To date, empirical work on heritage brands has only used origin date to manipulate the perception that a brand is a heritage brand. As heritage branding involves origin and history, it was important for us to demonstrate that era-specific associations actually differ as a function of the brand’s age. We found this was the case. Knowing nothing about a product other than the date of its production (2008, 1958, 1908, 1858, 1808, 1758) led consumers to view brands produced on or before 1908 as being likelier to be handmade, by an artisan, with expertise, and with pride (F(5, 63) = 16.670, p = .001). Yet, if age were the sole predictor of heritage, then we would expect no effect of heritage judgments to emerge in the absence of an age cue. A subsequent pilot test suggests this is not the case. Indeed, differences in judgments of a brand’s heritage also emerges based on the product category in which it operates suggesting that individuals use associations unrelated to age as a basis for heritage judgments (F(4,277, 45) = 19.061, p = <.001). (The statistic reported is based on a repeated-measures ANOVA wherein the assumption of sphe-
ricity has been violated. Consequently, the reported statistic is the Greenhouse-Geisser correction.

Building on the previous experiment, Study 2 sought to answer whether heritage judgments are based not just on *when* a brand began but also *how* it began. In other words, this study investigated the role of a brand’s origin in establishing its heritage. Specifically, study 2A tested whether internal (e.g., adhering to the values and intent of the founder) versus external (e.g., adhering to the desires of the consumer) motivations affect heritage perceptions, and found evidence that when brand’s adherence to internal motivations they are deemed more of a heritage brand than when they cater to consumer preferences. Consistent with our predictions, when the brand operated based on internal motivations, judgments of heritage were higher ($M = 5.66, SD = 1.122$) than when the brand’s identity was externally formed ($M = 5.12, SD = 1.044$; $t(133) = 2.89, p = .004$).

With this split between origin date and other information surrounding brand origins in mind, Study 2B investigated whether emphasizing these ‘internally-motivated’ attributes for a company could overwhelm origin date associations. This is exactly what we found. When we emphasized a company’s internal motivation, brands were seen as more of a *heritage brand*—irrespective of having been founded in 1908, 1958 or 2008—than an externally-motivated brand whose production was conducted of the same exact products at each company origin date ($F(1, 161) = 33.33, p < .001$; Cohen’s $d = 0.78$).

Studies 1-2 are concerned with production at company origin and study 3 how product origins translate to the current day. But if psychological essence is a contributing component outside of affecting product perception, other manipulations of psychological essence should be powerful in attenuating a company’s claim to heritage. As psychological essence is commonly viewed to transfer within families (Dur-Nimrod and Heine 2011; Keller 2005; Uhlmann, Zhu, Pizarro and Bloom 2012), we manipulated whether a family company had transferred ownership only within family or outside of it; and further whether ownership had been transferred only once or five times (holding time periods constant). Consistent with the idea that psychological essence transfer is key in judgments of heritage, family-owned companies were seen possessing equal heritage regardless of exchange frequency. However, one transfer outside the family was enough to attenuate heritage judgments and five transfers resulted in a larger drop ($F(1, 290) = 5.46, p = .029$).

In sum, we find that era-specific associations contribute to judgments of ‘heritage’ to the extent they signal origins. Further, when there is a disruption between company origin and present (in product or ownership), the brand experiences a detriment to its credence as a ‘heritage brand’. This work confirms prior work showing that consumers readily distinguish between heritage and non-heritage brands as well as show consistent patterns in their judgments of heritage.

**How Solitude Helps Essence Retention and Increases Demand for a Creator’s Product**

**EXTENDED ABSTRACT**

Artists and creators often communicate about their lives and the creative process through social and mainstream media. This information can affect consumers’ perceptions of an artist’s essence and the products they create.

According to Gelman (Gelman 2004; 2013; Medin and Ortony 1989), essence captures something fundamental that distinguishes an entity from others. An artist’s essence captures an underlying structure of beliefs about how they create, and how their innate potential for creativity is expressed under optimal conditions. Although unobservable, consumers’ views of this essence are nevertheless affected by how the artists are portrayed in the media. Specifically, artists are perceived to have greater essence when they embrace solitude in the process of creation, and people find their creations to be more authentic and desirable in this context.

Creativity could emerge through contact with others or in solitude. Given that social contact increases susceptibility to social expectations and obligations and increases feelings of self-inauthenticity (Wood et al. 2018; Baumeister 1987), consumers might assume that avoiding social contact (i.e., solitude) will increase artistic authenticity through a process of essence containment.

To elaborate: A solitary artist’s creation will be perceived to contain more of the creator’s essence because social contact (i.e., influence) leads to an attenuation of the original essence. Just as a brand’s essence is perceived to get weaker the further the production is from the original factories (Newman and Dhar 2014), so also does the unique essence of the creator get attenuated in the presence of others because of the perceived social influence of non-original agents. Thus, the more solitary the artist, the greater the essence left intact for transfer to their creations and the greater the perceptions of creative authenticity and demand.

Two pretests tested the assumption that solitary (versus sociable) individuals retain more of their original essence. 119 participants who saw a picture of a male walking alone or alongside a woman perceived him as having more essence when he was alone ($M = 71\%$) than when he was not ($M = 62\%$, $F(1, 117) = 4.73, p = .03$). An additional 354 participants perceived a man to be less susceptible to social influence when he was described as seeking solitude ($M = 2.33$) than as sociable ($M = 4.88$, $F(1, 352) = 391.93, p < .01$). He also retained greater essence in the former condition (76%) than in the latter (60%), $F(1, 352) = 42.6$, $p < .01$. Perceived susceptibility to social influence fully mediated the effect of solitude on essence left intact (95% CI [4.02, 9.37]).

Experiment 1 examined if solitude helps retain a creator’s essence and is then transferred to their creations. 147 participants read a biography of a painter described as being either solitary or sociable and then indicated how much of his original essence he had intact, rated two paintings by him, and indicated the extent to which his essence had transferred to these paintings (Smith, Newman, and Dhar 2016). The solitary artist had a greater amount of essence ($M = 5.57$) compared to the sociable artist ($M = 1.52$, $F(1, 137) = 367.64, p < .01$) and was also believed to have transferred more of his essence to his paintings ($M = 6.22$) than the sociable one ($M = 5.35$, $F(1, 137) = 10.47, p < .01$). The amount of original essence left intact inside the artist fully mediated the relationship between the artist’s social nature and essence transfer to the paintings (95% CI [.00, .81]).

Experiment 2 examined if this essence transfer affected consumers’ purchase intent. 122 participants read an article about a perfumer described as either solitary or sociable and then indicated the perceived creative authenticity of his perfumes (Valsesia, Nunes, and Ordanini 2016), amount of essence transferred to his perfumes, and likelihood of purchasing his perfumes. Participants indicated a greater purchase likelihood for perfumes created by a solitary perfumer ($M = 5.03$) than by a sociable perfumer ($M = 4.52$, $F(1, 116) = 4.17, p = .04$). This relationship was sequentially mediated by perceived amount of essence transferred to the perfume and creative authenticity of the perfume (95% CI [.01, .13]).

Experiment 3 ($N = 122$) was identical to Experiment 2 but with the addition of measures of perfumer’s expertise and effort invested in the creation to rule out alternative explanations. Purchase intentions were higher when the creator sought solitude ($M = 6.07$) than social connections ($M = 5.54$, $F(1, 120) = 3.28, p = .07$). Similarly, participants presumed greater essence transfer to the creation in the
former condition ($M = 6.78$) than in the latter ($M = 5.81$), $F(1,120) = 7.43, p < .01$. Parallel mediation analysis revealed that perceived effort invested and expertise did not mediate the relationship. However, the essence transferred from the artist to the perfumes significantly mediated the relationship between the perfumer’s desire for solitude and consumers’ purchase intent (95% CI [.02, .27]).

Solitude could be sought voluntarily during the creative process or be an inherent personality trait. People typically seek solitude (i.e., it is self-chosen) whereas loneliness is a state imposed by others and, therefore, might have different effects. To evaluate these possibilities, some participants in Experiment 4 ($N = 351$) read a description of a perfumer as having a solitary, lonely, or sociable personality. Others read about the perfumer experiencing solitude, loneliness or social connections during the creative process. The interaction of the artist’s nature and the focus of the description (personality vs. creative process) was marginally significant, $F(2, 345) = 2.485, p = .085$. Participants indicated greater purchase intentions when the creative process was solitary ($M = 6.36$) than when it was either lonely ($M = 5.45; F(1, 345) = 7.598, p < .01$) or sociable ($M = 5.68; F(1, 345) = 4.268, p = .04$). However, purchase intent did not vary with the artist’s personality (5.62, 5.72, and 5.59, respectively; $p = .90$).

To summarize: Portraying creators as seeking solitude leads to perceptions that their creations are more likely to be imbued with their essence, and this increases purchase intent.

When Heritage Branding Limits Consumer Desire for Innovation

EXTENDED ABSTRACT

One way in which brands enhance product appeal is through heritage branding—wherein, a product’s history or origin is made central to its identity. Although prior work has focused on the benefits of highlighting product history on consumer valuation (Wuestefeld et al. 2012) and on perceptions of the product’s authenticity or degree of “brand essence” (Beverland et al. 2008; Grayson and Martinec 2004; Newman and Dhar 2014), this article explores a cost of heritage associations. For example, Converse’s Chuck Taylors has benefited from its well-known history, with a design touted to have been unchanged for 100 years; at the same time, this positioning has made it challenging for the company to make desired improvements to the shoe.

Across six studies, we find that changes made to heritage-branded products, even those that functionally enhance the product, may decrease perceived value. Drawing on the design stance (Bloom 1996; Barrett, Laurence, and Margolis 2008), which asserts that people tend to define artifacts based on the perceived intentions behind their creation, in addition to work on the role of essentialist reasoning in authenticity judgments (Newman and Dhar 2014), we theorize that heritage branding leads consumers to define a product in relation to the original intentions behind its creation. In other words, heritage-branding ties a product’s essence directly to that which was present at its origins. Enhancements often deviate from the product’s original intent, leading consumers to view the product as no longer being true to its origins, and, as a result, less authentic. Thus, enhancements can actually decrease the perceived value of the product through lowering authenticity perceptions.

Study 1 provided initial evidence that enhancements can lower the value of heritage-branded products. Participants rated a set of high heritage-branded products (e.g., Campbell’s Soup) or a matched set of low heritage-branded products (e.g., Progresso Soup). Those who evaluated the high heritage products were significantly less willing to try new and improved versions than those who evaluated low heritage products, $t(218) = 4.31, p < .001$.

Study 2 then directly manipulated heritage branding and product enhancement. Participants viewed an ad for a burger restaurant with heritage branding manipulated by including or excluding indexical cues (e.g., est. date, lineage of founder, etc.) (Beverland et al. 2008; Grayson and Martinec 2004). Moreover, participants were randomly assigned to rate a burger that was either unchanged or enhanced from the original. As predicted, there was a significant interaction between heritage and enhancement on willingness to purchase the burger, $F(1, 360) = 10.23, p = .002$. When heritage branding was high, purchase intent was significantly more likely for the original than for the enhanced burger, $t(166) = 4.89, p = .03$. The pattern reversed when heritage branding was low, $t(193) = 5.47, p = .02$. Authenticity mediated this interaction (95% CI for indirect effect = -.165 to -.58) but not perceptions of quality.

Study 3 sought to increase external validity by testing whether the effect of heritage branding obtains for consequential choices. Participants read a description of a music ensemble. The description either highlighted the ensemble’s heritage (condition) or not (control condition). Then, all participants were asked to choose between an original version of the ensemble’s album or a remastered version of the same album. Participants were also informed that the study was incentive compatible in that a set of them would be randomly selected to actually receive the album they chose. Results revealed that participants were less likely to choose the remastered album (54.0%) when the heritage of the ensemble was highlighted compared to when it was not (67.3%), $\chi^2(1, N = 400) = 7.40, p = .007$.

Study 4 ruled out a salient alternative explanation—the backlash to enhancement could be driven by the fact the original is seen as having “stood the test of time,” and hence is rationally inferred to be of higher quality than the enhanced product. Between-subjects, we manipulated whether a heritage-branded jacket had existed for a relatively long (100 years) or short (10 years) amount of time. Participants expressed greater purchase interest for the original jacket $F(1, 556) = 5.93, p = .015, d = .20$. Importantly, there was no significant two-way interaction of time and product, $F(1, 556) = .23, p = .63$; nor was there a main effect of time, $F(1, 556) = 1.99, p = .16$. This suggests that, holding heritage branding constant, whether the product has a short or a long history does not alter the negative effect of enhancement on product valuations. Replicating Study 2, the main effect of enhancement was mediated by perceptions of authenticity (Indirect effect $= -.14$, 95% CI $= -.03$ to $-.27$).

Study 5 examined a boundary condition of the effect. Specifically, we reasoned that if consumers are primarily concerned with a product’s utilitarian features, then participants should be less concerned with the product’s authenticity, and hence, the negative effect of product enhancements should be attenuated. To test this, participants were told that they were interested in finding either an aesthetically-pleasing (hedonic goal) or a functional (utilitarian goal) chair, and evaluated either the original or enhanced version of it. As predicted, there was a significant interaction between the goal and enhancement, $F(1, 365) = 6.33, p = .012$. Although we replicated the negative effect of enhancement, $F(1,180) = 4.55, p = .03$, and mediation by perceptions of authenticity in hedonic goal condition (95% CI for indirect effect $= -.93$ to $-.19$), enhancement did not significantly alter product evaluation in the utilitarian goal condition, $F(1,185) = 1.99, p = .16$.

Finally, Study 6 tested whether the same effects manifest in hedonic experiences. Participants watched a clip from The Lion King...
that was either described as a bonus scene, added after the original production, or as a deleted scene, made during the original production of the film. Participants rated the same clip less enjoyable when it was described as a bonus scene as opposed to a deleted scene, $F(1,154) = 7.22, p = .008$. This effect was again mediated by perceptions of authenticity [estimated indirect effect= -.35; 95% CI= -0.72 to -.03].

Preserving Essence: The Mere Packaging Effect

EXTENDED ABSTRACT

Sustainability has become increasingly important for all stakeholders (Kumar, Rahman, Kazmi, and Goyal 2012), yet packaging constitutes almost one-third of US household waste (EPA 2015). In this research, we examine the psychological benefits of packaging that make it difficult to reduce in the marketplace.

Though packaging sometimes offers important functions (Kotler and Keller 2011), we examine if consumers prefer products that are packaged, even when it offers little to no functional benefits (“mere” packaging). Indeed, for the ten products we used, a pretest revealed that consumers do not believe packaging is necessary ($p < .01$). We hypothesize that packaging can be merely a psychological barrier. Psychologically, packaging can counteract negative product evaluations caused by contamination (Argo, Dahl, and Morales 2006). However, disgusting properties can infect even a properly packaged product (Morales and Fitzsimons 2007). Thus, concerns about contagion alone are not sufficient to explain the psychological benefits of mere packaging. Parallel to the contagion account, however, packaging might act as a barrier that prevents “essence” from escaping the product. Consumers imagine essence following the laws of physics—it can be depleted (Nemeroff and Rozin 2018)—and transferred even without physical touch (Morales, Dahl, and Argo 2018). Thus, reducing mere packaging might be impractical because consumers believe an unpackaged product’s essence has escaped. We find support for this hypothesis in 4 experiments using products that a pretest confirmed did not require packaging.

Study 1: In two experiments designed to see if consumers favor products with mere packaging, 172 students (study 1a) and 141 students (study 1b) engaged in a hypothetical shopping scenario for a soccer ball (1a) or USB drive (1b). Participants were told to imagine that they took the ball out of the packaging and had to be removed to inspect the ball. This allowed us to detect a moderator of the preference for packaging. In one condition, participants were told that the store only carried packaged balls and that the package had to be removed to inspect the ball. This allowed us to detect a moderator of the preference for packaging. In one case, participants were told to imagine that they took the ball out of the packaging themselves while in the other, it was the salesperson that opened the packaging. In all conditions, participants indicated whether they would choose a packaged version of the product, the unpackaged version that was examined, or were indifferent. In study 1a, there was a significant relationship between condition and frequency that the packaged product was chosen, $\chi^2(4, 172) = 23.527, p < .001$. As predicted, consumers strongly preferred a merely packaged ball (79% vs. 16% unpackaged) when given a choice between the two. If the consumer or salesperson removed the packaging, the preference for a packaged product was significantly reduced. Only 44% preferred the packaged product (vs. 40% unpackaged) when the salesperson opened it and only 39% when they opened it themselves (vs. 41% unpackaged). Study 1b replicates the findings from study 1a. A significant relationship between conditions and frequency of the packaged product being chosen was revealed, $\chi^2(2, 141) = 33.927, p < .001$. If the product was available packaged and unpackaged, participants chose the packaged option significantly more often than the unpackaged option (86% vs. 10%). The preference for a packaged item was greatly reduced if the packaging was opened at the point of purchase (42% vs. 38%). In sum, study 1 shows that consumers prefer merely packaged products over unpackaged ones. However, consumers are willing to choose unpackaged products significantly more often if they participate in removing the packaging at the point of purchase. We suspect that seeing the product opened at the point of purchase provides consumers with the reassurance that the essence has not escaped before. Study 2 explores this hypothesis.

Study 2: Study 2 explores if people perceive packaging as a way to prevent essence from leaving a product. Because consumers imagine that essence is like a depletable physical substance, we hypothesize that an unpackaged product will be perceived as less heavy compared to a packaged version. 193 participants engaged in 2 (between subjects; product in packaging vs. product next to packaging) x 8 (within subjects; product) mixed study design. All eight products were evaluated either in packaging or next to packaging. Across both between-subjects conditions, participants compared the value/weight of a product at hand and all of its packaging to an average version of the product and packaging on a 7-point scale (1, much less valuable than the average ___ and packaging; 7, much more valuable than the average ___ and packaging). As predicted, there was a significant difference between the two conditions for both weight ($F(1, 190) = 4.991, p < .05$) and value ($F(1, 190) = 4.087, p < .05$). Importantly, participants indicated that products and packaging are heavier and more valuable if the product was in the packaging ($M_{weight} = 4.65$; $M_{value} = 4.65$) compared to next to packaging ($M_{weight} = 4.37$; $M_{value} = 4.42$). A posttest ($n = 154$) revealed that products next to packaging are perceived as more contaminated ($p < .001$) but not lower quality ($p > .05$) or less safe ($p > .1$) compared to products inside packaging. Study 2 shows that mere packaging offers psychological benefits beyond protecting against (irrational) contagion. Participants believed that the unpackaged product with its packaging was lighter than when it was packaged, showing that essence is perceived as lost when packaging is removed and that this negatively impacts the value of the product in the consumer’s eyes.

While contagion research explains the devaluation of products with the transfer of unwanted properties into a target product, we find that the transfer of something out of the product is also a critical driver of product valuation. Mere packaging serves as a bidirectional barrier, keeping an object’s (positive) qualities inside while keeping the (negative) qualities of others out. By allowing consumers the opportunity to control unpackaging, we can reduce concerns about essence loss and possibly reduce the amount of nonfunctional packaging that ends up in landfills.

REFERENCES

SESSION OVERVIEW

A century of accumulated wisdom has given us ways to communicate a product’s experience and credence attributes through search attributes like brand name, price, and packaging. A typical ad or product information will include some combination of sound, sight, and semantics. In this session, we bring together nascent research that explores the following question from different angles, yet in a synergistic way: How do music (sound), pictures (sight), and verbal elements (semantics) in marketing communication influence both judgments of abstract notions, such as product personality, effectiveness or naturalness as well as perceptions of physical properties (e.g., quantity)? While this question is as old as marketing itself (“the old glasses”), this session combines four papers that uncover novel consumer associations and perceptual mechanisms (“the new wine”).

The first paper focuses on sound, which has received very little attention in consumer research (e.g., Krishna and Schwarz 2014) despite its prevalence in the marketplace. Melzner and Raghubir show across nine studies that timbres (the unique sounds of instruments) trigger specific associations of ruggedness and sophistication that can influence product perceptions with consequences for purchase intentions and donation amounts. They further show that this spill-over effect is moderated by the ambiguity of a priori product associations.

The second paper investigates visual advertising techniques (sight) on ad persuasiveness. Cian, Longoni, and Krishna compare ads that visualize a desired transformation either via before/after visuals (e.g., of a weight loss program) with ads that also include intermediate steps of progression. In seven studies they show that while progression ads are less prevalent, they facilitate mental simulation of the change process. This increased spontaneous generation of visual process imagery increases ad persuasiveness.

The last two papers examine semantics. Scekic and Krishna explore a novel association between the concepts of naturalness and size. In four studies they demonstrate the existence of a “small=natural” association. They show that consumers use descriptions of company size as a cue to infer product naturalness, suggesting that small companies can benefit from signaling their size, since consumers tend to prefer natural products (Rozin et al., 2004).

The last paper by Monnier and Thomas investigates verbal descriptions of size. In the context of online grocery shopping, they show in five studies that more versus less perceptual quantity descriptors (e.g., 12 snack bags of cookies1 oz each versus 12 oz of cookies in snack bags, 1 oz each) lead to a greater focus on hedonic satisfaction with rather than analytic evaluation of quantity. Consistent with this account, they find that retailers charge higher per unit prices and consumers evaluate prices more favorably when quantity information is framed more perceptually.

Together, these papers hone in on understanding how sound, sight, and semantics can affect product perceptions, ad persuasiveness, consumer inferences, and price evaluations. This session should be of interest to a broad audience of researchers with substantive interests in retailing and advertising as well as a theoretical interest in information processing and integration. The consequential nature of the dependent variables provides insights for practitioners.

The Sound of Music:
The Influence of Timbre on Product Perception

EXTENDED ABSTRACT

Does the distinctive sound of an instrument trigger specific associations and can these in turn affect product perceptions? Despite the omnipresence of music in the marketplace, research on musical features in marketing is relatively sparse. The present research focuses on timbre, the feature that determines “what music sounds like.” Timbre denotes features of auditory sensation that enable a listener to tell two sounds apart even when loudness, pitch, and duration are held constant. Timbre is an ecologically relevant cue allowing humans to differentiate between literally hundreds of voices, and instruments, regardless of musical proficiency.

Studies 1-3 examine pure associations with timbre. Study 1 finds that the e-guitar and the violin are associated with ruggedness and sophistication when presented in isolation (Study 1). Study 2 showed that while the mere name of the instrument led to the same pattern, it was exacerbated when the sound was presented instead. Study 3 show that the e-guitar and violin timbre do not trigger these associations due to their prototypicality for the rock and classic genre respectively, but rather that timbre is a significant contributor to genre specific associations.

Studies 4A-D demonstrates that associations triggered by timbre affect product perception, especially when the a priori associations with a product are ambiguous. The ambiguity is resolved by perceiving the product in accordance with timbre associations. However, when there is an a priori dominant association, congruent timbre can enhance the dominant association, while incongruent associations leave product perceptions largely unaffected. Studies 5-6 investigate downstream consequences.

Study 1 (N=99). Participants heard a tone played by a violin, e-guitar, or an artificial sine wave and rated how strongly they associated the sound with the five dimensions of brand personality (Aaker 1997). A 3(timbre: e-guitar, violin, sine) x 5(association: competence, excitement, ruggedness, sincerity, and sophistication) mixed-design ANOVA revealed an interaction, F(6.86, 329.33)=32.13, p<.001. While there were no strong associations with the sine wave, the e-guitar (violin) was most strongly associated with ruggedness (sophistication), ps<.001.

Study 2 (N =76). Students heard either the sound or saw the name of a violin or e-guitar and indicated their associations. A 2(instrument) x 2(information: timbre/name) x 2(association: ruggedness/sophistication) mixed-design ANOVA revealed a three-way
interaction, \(F(1,72)=10.82, p=.002\). Violins were more strongly associated with sophistication than ruggedness, with the reverse for e-guitars (\(p<.001\)), but the effects were stronger when the sound was heard (versus name shown).

Study 3 (\(N=327\)). Participants heard an excerpt of a well-known classical or rock genre piece either arranged for violins, e-guitars or sine waves. A(3)(timbre: e-guitar, violin, sine) x 2(song: Classical--Beethoven’s-5th, Rock--Smoke-on-the-water) x 2(association: ruggedness, sophistication) mixed-design ANOVA revealed the predicted three-way interaction, \(F(2, 321)=5.20, p=.006\). When presented with the sine wave, the rock (classical) piece was perceived as more rugged (sophisticated), \(p<.001\), reflecting pure genre associations. Presenting the piece with genre congruent timbre increased respective dominant associations (ruggedness-rock; sophistication-classical) compared to presentation with the sine tone, \(p<.001\). However, presenting the piece with genre incongruent timbre significantly increased timbre specific associations, \(p<.001\), such that for instance Beethoven’s-5th was perceived as more rugged than sophisticated when performed using the e-guitar.

Studies 4A-D (\(N_{\text{total}}=646\)): In all studies participants heard a violin/ e-guitar or no sound in a short product video and judged a product’s level of ruggedness and sophistication. There was a sound-association interaction in Studies A-C (\(F(2, 73)=4.02, p=.022; \ F(1, 63)=12.66, p<.001; \ F(2, 88)=2.72, p=.072\, A-C respectively). When a priori associations of ruggedness and sophistication were the same (perfume: 4A, control condition, \(p=.333\)), participants perceived the product as more rugged versus sophisticated when presented with the sound of an e-guitar, \(p>.001\), and the reverse was true when it was presented with a violin, \(p>.049\). When the product was perceived as more rugged (sophisticated), in the no sound condition (t-shirt: 3B, bathrobe: 3C; \(p<.001\)), the product was perceived as even more rugged (sophisticated) when presented with an e-guitar (violin) sound, \(p=.016\) (\(p=.092\)). Incongruent timbre did not affect product perceptions as compared to the control condition. Study 4D successfully replicated the results of studies 3A and B in a single design: A(2)(timbre: e-guitar, violin) x 2(product: perfume, t-shirt) x 2(association: ruggedness, sophistication) mixed-design ANOVA revealed a three-way interaction, \(F(1, 395)=7.17, p=.008\). The perfume was perceived as more rugged (sophisticated) than sophisticated (rugged) when presented with an e-guitar, \(p<.001\) (violin, \(p<.001\)), replicating Study 4A. The t-shirt (\(a\ priori\) more rugged) was perceived as more rugged than sophisticated when presented with an e-guitar (\(p<.001\)), and this pattern persisted but was attenuated when it was presented with a violin (\(p=.011\)), replicating Study 4B.

Study 5 (\(N=390\)) investigated downstream consequences. Participants were asked to imagine that they needed a new t-shirt to wear either to a fashionable fundraiser or an outdoorsy hiking trip and saw a video of the t-shirt with either the sound of a violin or e-guitar. 2(timbre: e-guitar/violin) x 2(scenario: fancy/outdoorsy) ANOVAs revealed the predicted interaction for purchase intention, \(F(1,386)=6.72, p=.010.\) Participants in the e-guitar condition indicated higher purchase intentions (similar patterns for evaluation and PWP) when presented with the outdoorsy versus fancy scenario, \(p=.018\). Similar directional effects were obtained for the violin condition.

Study 6 (\(N=193\)): Participants saw a video of one of two charities proteted to be higher in sophistication (Museums) or ruggedness (National Parks) alongside a melody played by either a violin or e-guitar and given the choice to donate part of their participation payment. A(2)(NGO) x 2(Timbre) between-subjects ANOVA on donation amount contingent on donating revealed a significant cross-over interaction, \(F(1,118)=4.39, p=.036\). Participants donated more to the Museums when a violin played, \(p=.019\), though there was no difference in donations to the Parks. Likelihood of donating did not differ. Future research will examine the potential moderating effect of \(a\ priori\) preference (higher for Parks) in explaining these results.

Together, these studies shed light on a neglected musical design feature that can be strategically used in marketing communication in order to affect consumer perceptions. Our findings advance research in musicology by suggesting timbre as a strong driver of genre associations.

**Imagery of Change: Visual Outcomes Elicit Process Simulation and Promote Persuasiveness**

**EXTENDED ABSTRACT**

Humans often desire change: we want to be thinner, look younger, have more hair. Marketers respond to such desires by offering products promising to deliver the corresponding changes: weight-loss programs, wrinkle removers, hair regrowth solutions. The visuals in the advertisements (ads) for these products typically focus on the desired final outcome by featuring a before and an after visual (e.g., a person at the beginning and at the end of a weight loss program; before-after ads). Very few change-ads include visuals of the intermediate steps between the before and the highly desirable after (e.g., a person gradually slimming down throughout the weight loss program; progression ads).

Although neglected in the marketplace and by future marketers, across seven studies we show that progression ads are superior to before-after ads across multiple consumer domains. We theorize that, to be effective, ads promising transformation should facilitate mental imagery of the trajectory of the change, i.e., the consumer should be able to imagine herself going through the transformation from “before” to “after.” Progression ads (but not before-after ads) evoke this kind of spontaneous process imagery: thoughts and images about the means and ways leading to a change. In turn, spontaneous process imagery increases the persuasiveness of the ad.

A content analysis of 250 ads of the top five weight-loss programs in the US showed that before-after ads are more common than progression ads: 36% were “before-after” whereas only 0.8% were “progression.” Another pilot study asked participants (\(N=122\)) to draw the ad for a weight loss program. Whereas 22.95% of participants drew before-after ads, only 1.64% drew progression ads (\(p<.001\); remaining ads coded as “others”). Overall, these pilot studies showed that progression ads are neglected by both current and future marketers.

Studies 1 and 2 test for the predicted ad-type effect: ad-type impacts real choice between products (study 1) and ad persuasiveness (study 2). Studies 3-5 focus on our process imagery explanation for this effect: progression ads evoke more process imagery than before-after ads (study 3); process imagery mediates the ad-type effect (studies 4-5); externally inducing process imagery attenuates the ad-type effect (study 6). Study 7 shows under which conditions utilizing progression ads may backfire. We also test alternative explanations for the ad-type effect: perceived effort in study 4 and amount of information in study 5.

Study 1 (\(N=131\)). In an incentive-compatible setting, students chose a free sample of a teeth whitening treatment promoted either by a before-after or by a progression ad. Whereas 67.2% of students chose the sample promoted by the progression ads, only 32.8% chose the sample promoted by the before-after ad (\(p<.01\)).

Study 2 (\(N=158\)). Participants rated the persuasiveness of one two ads (before-after vs. progression) for a hair growth product. The
Do Firm Cues Impact Product Perceptions?: When Small is Natural

EXTENDED ABSTRACT

Much research has connected product cues with product perceptions. Yet, research investigating the relationship between firm cues and product perceptions is limited. We study whether intrinsic firm characteristics influence product attribute perceptions – specifically, whether firm size influences perception of product naturalness. This question is relevant, given a climate of frequent mergers and acquisitions, which make firms bigger and their size salient, and considering consumers’ preference for natural products (Rozin et al. 2004).

Research on naturalness has found the contagion principle (e.g., Rozin and Nemeroff 1990) greatly responsible for the perception of naturalness loss: mixing a natural entity with another (natural or not) entity was shown to “contaminate” and “denaturalize” it (Rozin 2005). Furthermore, the “processing history” of an entity was shown to have a higher impact on its perceived naturalness, than its “ingredients”. This suggests that two seemingly identical products could be perceived differently on “naturalness”, due to inferences regarding the type and quantity of processing they have gone through – hence, the environment (i.e., firm) in which, and by which, the products are processed matters.

Human intervention deprives natural entities of their essence, contaminating them with the essence of humans, machines and chemicals (Rozin et al. 2004). Thus, the more humans and machines an object comes in contact with, the less natural it will be. As such, we suggest that products from larger firms could be considered more likely to be “contaminated”, leading to a “smaller firm = more natural product” intuition. We believe this intuition is scaffolded on an implicit association of the broader concepts of size and naturalness (i.e., “small = natural”): indeed, one could argue that living organisms are closest to their completely pure and natural form when they are “born” (i.e., small), since as they grow, they are more likely to change and be “contaminated” by the environment and contact with other entities. We tested these predictions in four studies.

Study 1 (N=182) tested the association of firm size and perceived product naturalness, and the persistence of this association (by manipulating awareness). In a 2 (“small” vs. “large” firm) x 2 (“aware” vs. “unaware” of association), between-subject, lab study, participants were presented a set of towels, and provided a towel swatch. In the “small” (“large”) firm condition participants read the towels were produced by a “small company of 20000 employees” (“large company of 20000 employees”). In the “aware” condition, instructions stated we were studying the impact of company size on perceived naturalness. Participants indicated the percentages of organic cotton they believed the towels contained, using a 2-item constant sum scale (total 100%). Organic cotton percentage was our dependent variable. A manipulation check confirmed organic cotton was perceived as more natural (Morganic=5.24 vs. Mconventional=3.65; p<.01). Results showed a main effect of firm size on perceived naturalness (Msmall=44.07% vs. Mlarge=32.27%; F(1, 178)=17.82, p<.01), but no effect of awareness, nor their interaction (p>.30). This revealed an association between firm size and perceived naturalness, even when participants interact with same haptic stimuli across conditions, and whether attention is drawn to the association or not.

In study 2 (N=134) we manipulated firm size in a less explicit way. We asked MTurk participants to evaluate a soap, and manipulated firm size as in study 1 (“company of 20 employees” vs. “company of 20000 employees”) – however, we did not define the firm “small” or “large”. Participants indicated perceived percentages of “natural” vs. “artificial” soap ingredients. A manipulation check showed the firm was perceived as smaller in the “small” condition (Msmall=2.22 vs. Mlarge=4.85; p<.01). Results showed an effect of firm size on perceived naturalness (Msmall=61.82% vs. Mlarge=49.33%; F(1, 132)=8.13, p<.01), providing further evidence for the “smaller firm = more natural product” intuition.

Theoretically, and differently from prior research on mental simulation, we bring attention to an understudied yet important typology of mental imagery: spontaneous mental simulation of process (process imagery), and highlight its critical role in the persuasiveness of advertised change. Second, we add to the literature on processing matters.
In study 3 (N=221) we tested the effect of firm size on perceived naturalness when a signal of naturalness was on the packaging. In a 2 (“small” vs. “large”) firm x 2 (“organic label” vs. “no organic label”) on package), between-subject lab study, participants evaluated a yogurt on a 7-point scale (1=“Completely artificial”, 7=“Completely natural”). We manipulated firm size as in study 1. Results showed a main effect of firm size (Msmall=4.21 vs. Mlarge=3.79; F(1, 217)=6.20, p<.05), and label presence (Morganic_label=4.38 vs. Minorganic_label=3.62; F(1, 217)=20.48, p<.01) on perceived naturalness. Their interaction was not significant (p>.70). Planned contrasts suggested the firm size effect was stronger in the “no organic label” (Msmall=3.86 vs. Mlarge=3.38; p<.05) than the “organic label” condition (Msmall=4.56 vs. Mlarge=4.20; p>.10). Study 3 provides further evidence for the firm size impact on perceived naturalness, and shows that this effect weakens in presence of other naturalness cues.

In study 4 (N=113), we used the implicit association test (IAT) procedure to investigate whether people implicitly associate concepts of size and naturalness such that “small = natural” (“big = artificial”). Four words were used for the “natural” (organic, herbal, raw, unprocessed), “artificial” (synthetic, plastic, fabricated, processed), “small” (little, tiny, micro, smaller), and “big” (huge, large, giant, bigger) categories. Following standard IAT procedure (e.g., Greenwald et al. 2003; Cian et al. 2015), participants were presented with seven blocks: five practice and two main blocks. In the “congruent” main block, participants assigned words to the “natural or small”; or “artificial or big” categories. In the second, “incongruent” block, the categories were paired in the opposite way (i.e., “artificial or small”, “natural or big”). As per IAT assumptions, we expected categorization to be faster in the congruent block. Results showed the overall IAT effect was significant and response times were shorter in the congruent block (Mcongruent=209.24, t(112)=5.36, p<.01; Mincongruent=1039.95ms vs. Mincongruent=1225.02ms), providing evidence for the “small = natural” implicit association. We suggest this association contributes to the “smaller firm = more natural products” intuition.

We provide evidence for the “smaller firm = more natural product” intuition, suggesting that small firms could benefit from signaling their size to consumers when competing with larger firms. Furthermore, when undergoing mergers and acquisitions, firms should consider the possible impact on consumers’ perception of their products – once acquired by large firms, small firms’ products might suffer from a perception of “denaturalization”.

Perceptual Grounding of Quantity

EXTENDED ABSTRACT

Online grocery shopping is growing at a fast pace. Because of the sensory distance between shoppers and products, online shoppers have to rely on textual descriptions of products provided by retailers to make sense of quantity. Retailers can use more perceptual description of quantities (e.g., “12 snack bags of cookies, 1 oz each”) or less perceptual descriptions (e.g., “12 oz of cookies in snack bags, 1 oz each”). In this research, we examine how different types of textual descriptions—more perceptual descriptions versus less perceptual descriptions—influence consumers’ value perceptions. Our conceptualization is based on the literature on mental imagery. The literature on mental imagery and concreteness (MacInnis and Price 1987, Paivio 1990) has shown that mental imagery can affect moral judgments (Amit and Greene 2012), perceived likelihood of future events (Sherman et al. 1985), persuasion (Green and Brock 2000), preferences (Steinmetz, Tausen, and Risen 2018), product attractiveness (Adaval and Wyer 1998), anticipated satisfaction (Shiv and Huber 2000), willingness to pay (Bushong et al. 2010) and consumer choice (Huyge et al. 2017).

Based on this stream of research, we propose that mathematical units (ounces, pounds, etc.) are less perceptual than natural units (pieces, bags, etc.). Furthermore, we propose that product descriptions with more perceptual descriptions of quantity leads i) retailers to charge higher price per unit, and ii) consumers to make more favorable price judgments.

Study 1: Amazon publishes on its website the top 100 bestsellers per category. To test our first prediction, in study 1 we coded the top 100 bestsellers of five categories with products that contains either natural or mathematical unit of quantity (total of 474 observations when removing products with missing information). We found a significant main effect of unit type on price per unit (log), F(1, 461) = 12.85, p <.001, such that price per unit is higher for products with quantity expressed in natural (vs mathematical) unit.

Study 2. In study 2 (N = 217), we manipulated between subjects whether quantity is communicated in a more or less perceptual manner, with two replicates within subjects (i.e., potato chips and cookies). Participants were given the verbal description as well as the price of each product and asked to rate price attractiveness on a seven-point scale. For instance, for the chips replicate participants in the natural unit condition read “Snack size bags of potato chips, 12 bags (12 bags of 1 oz each)” while participants in the mathematical unit condition read “Snack size bags of potato chips, 12 oz (12 bags of 1 oz each)”. We also measured our mediator, satisfaction with quantity (“How satisfied are you with the quantity offered for this price?”, on a five-point scale. We found a main effect of the type of quantity description, F(1, 215) = 12.03, p <.001, such that price attractiveness was significantly higher in the more perceptual condition (M = 4.22) than in the less perceptual condition (M = 3.60). In addition, we found that the effect was mediated by satisfaction with quantity.

Study 3. In study 3 (N = 296), we show that the effect of mental imagery is moderated by construal mindset. We first measured participants’ natural construal mind-set before they responded to the study (BIF, Vallacher and Wegner 1989) in a supposedly unrelated task. Because individuals in a low level of construal tend to pay more attention to concrete details and rely on mental imagery (Amit and Green 2012; Fujita et al. 2006; Tsai and Thomas 2011), we conceptualize that ease of mental visualization matters more for individuals in concrete construal mindset. Accordingly, we found significant effects of type of quantity description, b = .79, p <.001, construal mindset, b = .03, p <.01, and a significant interaction between quantity framing and construal mindset, b = -.03, p <.05. The effect of perceptual quantity description is stronger for people with a low construal mindset (M + 3SD), b = 1.28, p <.001, but is attenuated for individuals with a high construal mindset (M + 3SD), b = .29, p =.15. A test of the moderated mediation model (model 7) showed that the interactive effect of construal level and quantity description is mediated by satisfaction with quantity.

Study 4. In study 4 (N = 152), we tested moderation by brand attitude. We suggest that more natural units render quantity easier to visualize, which in turn makes quantity judgments more hedonic (vs analytical) in nature. If this is the case, the positive effect of natural unit on price attractiveness should be attenuated when prior brand attitude is negative. Using six real brands with unit type and replicate manipulated within subjects, we found significant effects of unit type, b = .15, p <.02, brand liking, b = .25, p <.001, and a significant interaction, b = .09, p <.04. The effect of perceptual quantity description on price evaluation was significant when brand liking is high (M
Study 5. Lastly, if the effect of natural units is driven by greater reliance on hedonic (versus analytical) quantity evaluations, price judgments should be less sensitive to scope (Hsee and Rottenstreich 2004). In this study we used a completely within-subjects design (N = 108), wherein each participant evaluated 32 prices (16 products twice, each in both natural unit and mathematical unit conditions). We found significant effects of quantity description, $b = 1.04$, $p < .001$, quantity magnitude (log), $b = .40$, $p < .001$, and a significant interaction, $b = -.32$, $p = .001$, such that natural units improved price attractiveness when quantity magnitude was low ($M - 1SD$), $M$ more perceptual = 4.72, $M$ less perceptual = 4.16, $p < .001$, but not when quantity magnitude was high ($M + 1SD$), $M$ more perceptual = 4.85, $M$ less perceptual = 4.77, $p = .19$.

REFERENCES

The second two papers focus on simultaneous multiple goal pursuit and the tradeoffs this strategy can entail. Friedman, Han, Voichek, and Dhar examine situations in which setting a specific goal (e.g., donate a certain amount to a charity) can conflict with a higher-order goal (e.g., maximize effectiveness of donations). Five studies demonstrate that specific goals reduce attention to and valuation of outside options, decreasing the likelihood of switching to superior alternatives (i.e., more effective means). Finally, Woolley, Fishbach, and Wang focus on conflict that evolves from the simultaneous pursuit of health and social goals when eating. Six studies, including large-scale surveys and controlled experiments, show that a goal to manage food restrictions can interfere with social-relationship goals by causing people to feel lonelier.

Together, these papers shed new light on processes of sequential and simultaneous multiple goal pursuit. The findings point to unique challenges consumers face when pursuing multiple objectives and identify some strategies to increase success. This session should have broad appeal to scholars interested in goal pursuit, motivation, time, consumer well-being, and the connections between them.

**Budgeting Time First Increases Multiple Goal Achievement**

Consumers have only 24 hours a day to pursue their multiple goals. When time is effectively allocated across multiple goals, consumers achieve their objectives. But when time and goals are misaligned, goal failure ensues. On a workday, that last email gets sent, but family dinner is missed. On a weekend, the grocery shopping gets done, but a workout is cut short. Such goal failures produce undesirable outcomes, including negative affect, reduced motivation, and goal disengagement (Brunstein 1993; Jones et al. 2009; Smiley et al. 2016; Soman and Cheema 2004; Weingarten, Bhatia, and Mellers 2018).

Several factors contribute to goal-time misalignment. Consumers underestimate time requirements (Buehler, Griffin, and Ross 1994) and overestimate future time slack (Zauberman and Lynch 2005). People undermine deadlines (Ariely and Wertenbroch 2002) and overspend time on proximal goals (Jhang and Lynch 2015). Such biases are especially problematic for multiple goals, as errors compound over sequential goal pursuit (Fernbach, Kan, and Lynch 2015).

How, then, can consumers better marshal their time to achieve multiple goals? In this research, we propose that a subtle shift in how people think about their goals in relationship to time—namely, adopting a “time-first” mindset—can improve multiple goal achievement. Specifically, we predict that budgeting time before setting multiple goals (vs. not budgeting time or budgeting time after goal-setting) encourages consumers to better calibrate goals to available time (i.e., to set goals that can be achieved within the time available to pursue them). Consequently, we predict that putting time first will increase multiple goal achievement.

Four experiments test these predictions. Each followed a similar procedure. Participants were given a total amount of time to pursue multiple tasks and asked to set goals for each. Goal-setting was incentivized (through bonus pay) such that people should aim to set high, but achievable, goals on each task. They were randomly assigned to one of two conditions: time-first or control. In the time-first

**Time Matters: Dynamics of Sequential and Simultaneous Multiple Goal Pursuit**

**Chair:** Sarah Memmi, Duke University, USA

**SESSION OVERVIEW**

Multiple goal pursuit is a regular feature of consumers’ everyday lives. Over the course of a single day, a consumer might pursue multiple goals for work, family, and personal interests. Within a single consumption occasion, such as a meal, a consumer might pursue multiple goals for health, social connection, and enjoyment. Compared to the pursuit of a single, focal goal, multiple goal pursuit is more complex (Orehek and Vazeou-Nieuwenhuis 2013; Weingarten, Bhatia, and Mellers 2018) and requires a different set of decisions (Dhar and Simonson 1999; Fishbach and Dhar 2005).

One critical factor in multiple goal pursuit is time. Goal pursuit unfolds over time and is constrained by time (Etkin 2019). When goals are pursued sequentially, consumers must determine how to allocate their time and how to manage motivation over time and across multiple goals (Huang et al. 2015; Fernbach, Kan, and Lynch 2015). Simultaneous goal pursuit (i.e., single actions that satisfy multiple goals) makes efficient use of time, but also imposes constraints that can create conflict between goals (Köpetz et al. 2011; Srna, Schrift, and Zauberman 2017). While emerging research highlights the interplay between time and goal pursuit, many open questions remain. This session offers new wisdom on the complex relationship between multiple goals and time.

Four papers examine the dynamics of sequential and simultaneous multiple goal pursuit. The first two papers investigate sequential goal pursuit, focusing on the effects of planning. First, Memmi and Etkin examine how time budgeting influences multiple goal achievement. Four studies find that budgeting time before setting multiple goals encourages consumers to calibrate goals to available time and, consequently, increases multiple goal achievement. Suher, Huang, and Lee investigate how planning for multiple goals affects motivation throughout grocery shopping trips. Five shopper tracking studies demonstrate that planning for multiple subgoals (i.e., creating a shopping list) produces a monotonic reduction in motivation over time, whereas consumers who don’t plan purchases demonstrate a nonmonotonic “stuck in-the-middle” motivational pattern.

The second two papers focus on simultaneous multiple goal pursuit and the tradeoffs this strategy can entail. Friedman, Han, Voichek, and Dhar examine situations in which setting a specific goal (e.g., donate a certain amount to a charity) can conflict with a higher-order goal (e.g., maximize effectiveness of donations). Five studies demonstrate that specific goals reduce attention to and valuation of outside options, decreasing the likelihood of switching to superior alternatives (i.e., more effective means). Finally, Woolley, Fishbach, and Wang focus on conflict that evolves from the simultaneous pursuit of health and social goals when eating. Six studies, including large-scale surveys and controlled experiments, show that a goal to manage food restrictions can interfere with social-relationship goals by causing people to feel lonelier.

Together, these papers shed new light on processes of sequential and simultaneous multiple goal pursuit. The findings point to unique challenges consumers face when pursuing multiple objectives and identify some strategies to increase success. This session should have broad appeal to scholars interested in goal pursuit, motivation, time, consumer well-being, and the connections between them.

**EXTENDED ABSTRACT**

Consumers have only 24 hours a day to pursue their multiple goals. When time is effectively allocated across multiple goals, consumers achieve their objectives. But when time and goals are misaligned, goal failure ensues. On a workday, that last email gets sent, but family dinner is missed. On a weekend, the grocery shopping gets done, but a workout is cut short. Such goal failures produce undesirable outcomes, including negative affect, reduced motivation, and goal disengagement (Brunstein 1993; Jones et al. 2009; Smiley et al. 2016; Soman and Cheema 2004; Weingarten, Bhatia, and Mellers 2018).

Several factors contribute to goal-time misalignment. Consumers underestimate time requirements (Buehler, Griffin, and Ross 1994) and overestimate future time slack (Zauberman and Lynch 2005). People undermine deadlines (Ariely and Wertenbroch 2002) and overspend time on proximal goals (Jhang and Lynch 2015). Such biases are especially problematic for multiple goals, as errors compound over sequential goal pursuit (Fernbach, Kan, and Lynch 2015).

How, then, can consumers better marshal their time to achieve multiple goals? In this research, we propose that a subtle shift in how people think about their goals in relationship to time—namely, adopting a “time-first” mindset—can improve multiple goal achievement. Specifically, we predict that budgeting time before setting multiple goals (vs. not budgeting time or budgeting time after goal-setting) encourages consumers to better calibrate goals to available time (i.e., to set goals that can be achieved within the time available to pursue them). Consequently, we predict that putting time first will increase multiple goal achievement.

Four experiments test these predictions. Each followed a similar procedure. Participants were given a total amount of time to pursue multiple tasks and asked to set goals for each. Goal-setting was incentivized (through bonus pay) such that people should aim to set high, but achievable, goals on each task. They were randomly assigned to one of two conditions: time-first or control. In the time-first
condition, participants budgeted time to each task before setting a goal, whereas in the control condition, participants simply set goals. We measured what goals people set, rates of multiple goal achievement, and the discrepancy or difference between set goal levels and actual output (i.e., number of correct answers on each task).

In experiment 1 (N = 150), participants were given 7 total minutes to spend on three tasks (geography, spelling, and math quizzes). As predicted, budgeting time first improved goal-setting. Compared to the control, participants in the time-first condition set lower goals (p = .002) that they were more likely to achieve (total number of goals achieved: p = .002; likelihood of achieving all three goals: p = .012). Supporting our theory, this occurred because participants calibrated their goals based on the time available to pursue them. On average, all participants underperformed their goals (i.e., goals exceeded actual output, which did not differ across condition). But importantly, this discrepancy was significantly smaller in the time-first (vs. control) condition (p = .001). Thus, participants who budgeted time first still set challenging goals (i.e., goals that exceeded output), and motivating goals (i.e., goals that produced a comparable level of output), but were more achievable within the time available.

Experiment 2 (N = 300) tests an alternative explanation based on budgeting per se. The design replicated study 1, with the addition of a goals-first condition in which participants budgeted time across tasks after setting goals. Consistent with prior results, the time-first (vs. control) manipulation led to lower goals (M controls = 69.35 vs. M time-first = 56.63, p = .013) and increased multiple goal achievement (M controls = 1.92 vs. M time-first = 2.32, p = .012), without reducing overall output (M control = 52.23 vs. M time-first = 50.96, p = .687). Importantly, the goals-first condition did not differ from the control (p’s > .40). Supporting our theory, rather than merely planning how to spend time, putting time first benefits multiple goal achievement by calibrating goals in relation to time. A follow-up study showed that consumers who budget time after goal setting are unlikely to subsequently recalibrate goals, underscoring that time budgeting must occur before goal setting to boost multiple goal achievement.

Experiment 3 (N = 280) tests whether the effect is robust to assigned time budgeting. The design was the same as in experiment 1, except that participants in the time-first condition were all assigned to spend 3 (of the total 9) minutes on each task. Even when participants could not budget time based on individual preferences, setting goals in relation to time still encouraged lower goals (M controls = 76.80 vs. M time-first = 59.07, p < .001) and increased multiple goal achievement (M controls = 1.76 vs. M time-first = 2.07, p = .020), without reducing overall output (M controls = 51.42 vs. M time-first = 50.48, p = .685).

In experiment 4, we generalize to a consumer-relevant paradigm—a shopping spree. Lab participants (N = 103) set goals for how many real products (maximum $10/product) to shop for on Amazon.com and Target.com over a total of 7 minutes. Consistent with prior results, participants in the time-first condition set lower goals set (p = .003), were more likely to achieve both shopping goals (p < .001), and showed less goal-output discrepancy (p = .001), without reducing overall output (i.e., products selected; p = 638). Underscoring our theorizing regarding better calibrated (vs. generally lower) goals, budgeting more time to a store predicted higher shopping goals (Target: p = 1.13, p = .074; Amazon: p = 2.80, p < .001).

Together, these findings demonstrate that budgeting time before setting goals increases multiple goal achievement. Importantly, the time-first approach encouraged people to set more achievable goals, but it did not reduce (and sometimes even increased) overall output. Rather than merely eliciting lower goals, putting time first encourages better-calibrated goals that are equally (if not more) motivating and more likely to (all) be achieved. This research has substantive implications for consumer goal pursuit and well-being, and contributes to understanding of goal setting, the relationship between goals and time, resource budgeting, and multiple goal pursuit.

Planning for Multiple Shopping Goals in the Marketplace

EXTENDED ABSTRACT

An average consumer makes two grocery-shopping trips per week, amounting to over $600 billion sales in the United States alone (FMI 2018). The scale of this industry makes studying motivational dynamics that occur during a shopping trip (which is often comprised of multiple, sequential choices; Dhar, Huber, and Khan 2007; Kahn 2018) increasingly important. Furthermore, goals can also have a hierarchical structure (Kruglanski et al. 2002; Huang, Jin, and Zhang 2017). In this research, we connect goal hierarchy theory with findings on the temporal dynamics of goal pursuit to explore how consumer motivation evolves over the course of sequential choices in the marketplace (MSI 2018).

We focus on the grocery shopping domain, in which a consumer’s overall goal—to complete the shopping trip—is delineated by multiple sub-goals of specific items to purchase. Accordingly, whether a shopper uses a shopping list with specific sub-goals determines the structure of goal pursuit, which could lead to different motivational patterns over the course of grocery shopping. We used the amount of time shoppers spent between sequential product choices—i.e., inter-choice time—as a proxy for their motivation in the store (pilot tests verified the validity of this proxy measure: the more motivated a consumer was, the faster this consumer moved from one item to the next). Importantly, a field study and four online shopping experiments captured a shopping-list dependent dynamic pattern of consumer motivation.

In study 1, 250 shoppers at a grocery store participated in a video tracking study (N = 2,285 inter-choice times). We regressed inter-choice time on the cumulative trip duration at the moment of purchase (i.e., progress in the trip), the square of the trip duration, a contrast code for shopping list usage (List = 1; No-List = −1), and the two-way interactions between the list code and trip duration and the list code and squared trip duration with total purchase amount as a covariate. There was a positive interaction between squared trip duration and the list code (β = 0.0010, Wald χ^2(1959) = 34.58, p < .0001), suggesting that whether motivation (inter-choice time) followed a curvilinear trend depended on list usage. In the list condition, there was a positive linear effect of trip duration (β = 0.0247, Wald χ^2(1959) = 37.79, p < .0001), such that shoppers exhibited a monotonic decrease in motivation over the course of the trip. In the no-list condition, in contrast, we observed a negative quadratic effect of trip duration (β = −0.0023, Wald χ^2(1959) = 56.02, p < .0001), such that shoppers exhibited a nonmonotonic stuck-in-the-middle motivation pattern.

In study 2, we recruited 250 undergraduate students to complete an incentive-aligned shopping trip in one of two pre-trip planning conditions (list vs. no-list). In the list condition, participants received a budget of $35 and created a list of four or more categories. In the no-list condition, participants received the same instructions but did not create a list. The store included 15 grocery categories presented in a fixed order. The analysis procedure from study 1 (N = 1,835 inter-choice times) showed the same interaction between squared trip duration and the list contrast code (β = 2.2482, Wald χ^2(595) = 14.88, p = .0001). In the list condition, there was again a positive linear effect of trip duration (β = 0.7363, Wald χ^2(595) = 14.99, p = .0001). In the no-list condition, there was a negative quadratic effect.
of trip duration ($\beta = -3.6705$, Wald $\chi^2(595) = 14.92, p = .0001$). We further replicated these patterns with samples of frequent shoppers from Prolific, and with randomized category order and an externally generated list (replication studies with 120 participants and 211 participants, respectively).

In study 3, we recruited 184 participants from Prolific to complete an online shopping trip in one of three conditions: the same no-list condition, and two variations of the list condition to manipulate goal-progress reference points (i.e., to-date vs. to-go frames; Koo and Fishbach 2008). We hypothesized that the to-date condition would replicate patterns observed so far in the list conditions, as using a shopping list naturally directs shoppers’ attention to the items checked off from the list (i.e., a to-date frame, Koo and Fishbach 2008); hence, this should lead to a monotonic decrease in motivation as shoppers move away from the starting point and toward the end of the trip. Following this logic, the to-go list condition should result in an opposite pattern (i.e., a monotonic increase in motivation) by focusing shoppers on the end-point of the trip as the reference point. We followed the same analysis procedure with dummy coding of the pre-trip planning conditions. Consistent with the list conditions in previous studies, the to-date list condition again showed a positive effect of trip time (i.e., a monotonic decrease in motivation; $\beta = 3.1457$, Wald $\chi^2(1058) = 47.857, p < .0001$). In contrast, the to-go list condition showed a negative effect of trip time ($\beta = -4.6181$, Wald $\chi^2(1058) = 56.94, p < .0001$). Finally, the no-list condition again had a negative quadratic effect of trip time ($\beta = -4.0169$, Wald $\chi^2(1058) = 42.43, p < .0001$).

This work contributes to the understanding of shopper motivation in three critical ways. First, by employing novel methodologies in the field and online, we uncovered theoretical insights regarding how motivation to complete multiple sub-goals changes in shopping environments. Second, we add to the growing research on shopper psychology and behavior-tracking technology by drawing attention to one important antecedent of in-store behavior—shopping list usage. Third, our findings add to the dialogue that consumer motivation can follow either a linear trend (Kivetz, Urminsly, and Zheng 2006) or a curvilinear trend (Bonezzi, Brendl, and De Angelis 2011). In doing so, we demonstrate how the psychophysics of goal pursuit could apply to a multiple-goal context with consumer-generated goals in the marketplace. Furthermore, supplementary analysis demonstrates that the dynamics of shopper motivation may influence unplanned purchasing behavior. We encourage future research to further explore motivation dynamics across sequential choices and goal hierarchies in the marketplace.

**The Better Path Not Taken: Goal-Setting Undermines Opportunity Cost Consideration**

**EXTENDED ABSTRACT**

Consider two drivers who work on both Uber and Lyft rideshare services. One sets a goal to earn $50 on Lyft that evening, while the other does not. Both complete a few rides on Lyft before noticing that Uber has surge pricing, so they would earn more by switching to Uber’s platform. Which driver would be more likely to switch? A fundamental finding in the goals literature is that active goals will direct people’s choices (Brendl, Markman, and Messner 2003), and according to the value maximization principle, people will choose the option that offers the most utility (Simonson and Tversky 1992). In this work, we explore the interplay of goals and preferences to examine how goal setting can undermine achieving a more preferred outcome. We focus on scenarios like the example above, where the alternative option strictly dominates the status quo, and thus the chooser would be better off by switching. Across five studies, we demonstrate that people are less likely to switch to a dominant alternative when they set a goal versus when they do not.

Study 1 provides initial evidence that setting a goal can decrease one’s likelihood of switching to a preferred alternative option in a naturalistic setting. Participants on MTurk read a hypothetical scenario in which they had begun working on MTurk for the day, when they received an invitation for a spontaneous get-together. They rated their likelihood of attending the party instead of continuing to work on MTurk. On the next page, they indicated the extent to which they set a daily earning goal for MTurk. As predicted, participants’ likelihood of going to the enjoyable party was negatively correlated with the extent to which they set a daily earning goal ($r = -.38, p < .001$), providing initial evidence that setting a goal can decrease the likelihood of switching to more attractive outside opportunities. However, while the party scenario is on average more appealing than completing MTurk studies for small amounts of money, it is not objectively better on all dimensions. Further, the correlational design leaves the study open to alternative explanations.

To account for these issues, study 2 directly manipulated goal-setting in an incentive-compatible paradigm. Participants were tasked with solving anagrams, which paid 2 cents per correct answer. Half were then instructed to set a goal for the number of anagrams they expected to solve before commencing the anagram task. Before proceeding, all participants read about a word-counting task they could do instead, which would pay a 3-cent bonus and was a binary rather than free-response choice. They chose whether to continue with the anagram task or switch to the word-counting task. As predicted, we find that participants in the goal-setting condition were significantly less likely to switch to the more lucrative task ($31\%_{\text{goal}}$ vs. $45\%_{\text{no-goal}}$, $\chi^2 = 4.45, p = .035$), resulting in lower payment ($\$0.35_{\text{goal}}$ vs. $\$0.38_{\text{no-goal}}$, $F(1,198) = 6.05, p = .02$).

Study 3 tests the underlying mechanism of the effect. Specifically, we examine whether setting a goal decreases switching because of reduced attention to outside opportunities or devaluing the non-goal option. To do so, we added a step to the study 2 design, where participants chose whether or not to read about an alternative task, rather than being explicitly provided with that information. Again, participants with an anagram-goal were less likely to choose the dominant alternative than those without a goal ($24\%_{\text{goal}}$ vs. $53\%_{\text{no-goal}}$, $\chi^2 = 17.5, p < .001$). Further, we examined the proportion of participants who did not attend to the outside option, as well as the proportion that chose to switch conditional on reading about the alternative. We find that setting a goal decreased attention to outside alternatives: participants with an anagram-goal (56%) searched less than those without a goal (75%; $\chi^2 = 7.8, p = .005$). However, this does not entirely explain our effect. Even among those who searched and attended to the outside alternative, significantly more people without a goal (79%) switched to the dominant alternative than those with an anagram-goal (54%; $\chi^2 = 7.8, p = .005$), suggesting that the non-goal alternative is devalued in addition to receiving less attention.

Study 4a explores a boundary to our effect: setting broader goals that better accommodate the outside alternatives. All participants read a hypothetical scenario in which they made monthly donations to a charity providing vaccines to a third-world country. Participants in the narrow-goal condition read that they set a goal to donate a certain amount of money to that charity. Participants in the broad-goal condition read that they set a goal to save a certain number of lives through their donations. After donating to the initial charity for a few months, a more efficient charity solicits a request. Participants in the narrow-goal condition again were less likely to switch than those in
the no-goal condition (Mnarrow-goal = 5.8 vs. Mno-goal = 6.9, p = .001). Setting a broader goal moderates but does not fully attenuate this effect, as those in the broader goal condition were more likely to switch than those in the narrow-goal condition (Mbroad-goal = 6.4 vs. Mnarrow-goal = 5.8, p = .079) but still directionally less likely than those in the no-goal condition (Mbroad-goal = 6.4 vs. Mno-goal = 6.9, p = .148). Finally, study 4b replicates and extends this pattern of results to a different context at a gym. Participants read that they set either a broad (calories) or narrow (minutes) goal for a dispreferred exercise machine, and chose whether to switch when their preferred machine becomes available.

We thus demonstrate that setting a goal can decrease the likelihood of switching to a dominant alternative course of action across a variety of contexts, and across naturalistic, incentive-compatible, and hypothetical designs. We attribute this decreased switching to both decreased attention to and devaluing of non-goal alternatives. While setting broader goals dampens this effect, it does not fully attenuate it.

A Multi-Goal Approach to Food Consumption: How Food Restrictions Affect Social-Relationship Goals

EXTENDED ABSTRACT

When consuming food with others, consumers pursue multiple goals simultaneously. One of the primary goals of eating is to satisfy hunger, but eating a meal also brings people together, satisfying social-relationship goals (Ratner and Hamilton, 2015; Rozin 2005). Indeed, food consumption has important consequences for social connection and cooperation (Liberman, Woodward, Sullivan, and Kinzler 2016; Woolley and Fishbach 2017; 2019). The current research takes a multi-goal approach to food consumption, demonstrating how navigating nutritional and health goals when eating can impact the relationship goals consumers hold.

In particular, we examine the effect of dietary restrictions on social connection. Dietary restrictions are increasingly globally and affect both children and adults (Sicherer and Sampson 2018; Tang and Mullins 2017). Whereas existing research focused primarily on the clinical component of dietary restrictions, examining their prevalence, etiology, management, and treatment, we examine the psychosocial impact food restrictions can have for relationship goals. The current research accordingly investigated the influence of food restrictions on experienced social isolation (loneliness).

Using a multi-method approach including large-scale surveys and controlled experiments, we tested the novel prediction that exclusion from a meal, due to the presence of a food restriction, leads people to feel excluded from the social bond. In doing so, we draw on research from multiple disciplines, including psychology (Rozin 2005), anthropology (Fox 1994), and sociology (Fischler 1988), which have emphasized the social and cultural nature of food consumption. If food brings people together and strengthens bonds, by limiting the ability to share in a meal, food restrictions could limit one’s ability to share in the social bond as well.

The first three studies examined the association between food restriction (present vs. absent) and isolation. Study 1 used a nationally representative survey of 35,093 households conducted by the CDC that included a proxy measure of loneliness in children (i.e., child has difficulties getting along with others, is often depressed, and is unhappy or tearful). A regression analysis testing the prediction that food restrictions are associated with higher scores on the loneliness proxy measure resulted in a significant effect ($b = .21$, SE = .02, $t(35091) = 12.88$, $p < .001$). This association between food restrictions and children’s loneliness held when controlling for covariates typically associated with loneliness (i.e., age, gender, race/ethnicity, income).

Study 2 extended this finding, using a validated measure of observer reported loneliness in children (assessed via Asher, Hymel, and Renshaw 1984). We measured teachers’ reports of 710 students’ food restrictions and loneliness. Our analysis replicated Study 1, finding a significant association between reported food restriction and loneliness ($b = .34$, SE = .09, $t(702) = 2.69$, $p = .007$), which held when controlling for other covariates that predict loneliness in children.

In Study 3, we extended this finding to a sample of adults ($N = 495$), measuring the presence of food restriction and using a validated measure of loneliness in adults (Revised UCLA Loneliness Scale; Hughes et al. 2004). As in Studies 1-2, we found the predicted relationship between food restrictions and loneliness ($b = .30$, SE = .10, $t(493) = 3.62$, $p < .001$). Having a food restriction was associated with an increase in self-reported loneliness among adults, a pattern which held when controlling for other covariates associated with loneliness. This finding also held in a pre-registered direct replication ($N = 500$).

The next three studies tested the causal pathway between food restrictions and loneliness using controlled experiments. In Study 4, we assigned unrestricted participants in a lab study to experience a food restriction or not (i.e., they were restricted from drinking a beverage or they were not restricted) during a social interaction that could be construed as isolating. Those assigned a restriction (vs. not) reported feeling lonelier during the social interaction ($M_{restricted} = 3.88$; $M_{unrestricted} = 2.23$; $t(81) = 2.14$, $p = .035$), providing evidence that food restrictions cause loneliness.

In Study 5, we manipulated the salience of food restriction for unrestricted participants. Those with a pre-existing food restriction who were reminded of their restriction reported feeling lonelier than those who were also restricted, but were not reminded of their restriction ($M_{salience=2.95}; M_{no-salience}=2.26, t(158) = 3.11, p = .002$).

Study 6 capitalized on a naturally occurring manipulation of food restriction—the Jewish holiday of Passover when Jewish observers are restricted from eating chametz (leavened food). We surveyed observant Jewish participants who lived in a neighborhood where they were a small minority, and indeed, most reported eating meals with non-observant people. We assessed loneliness twice – first during Passover when participants were restricted, and again after Passover when participants were no longer restricted. As predicted, the effect of food restriction on loneliness replicated in this sample. Observant participants felt lonelier during Passover, when they experienced a food restriction, than after ($M_{Passover}=2.66; M_{after}=2.04, t(40) = 2.75, p = .009$).

One remaining question is whether there is a kernel of truth in feeling isolated as a result of food restrictions: Do people actually exclude others who have food restrictions? To answer this, we asked unrestricted participants to select a person to play an online game with them. Participants chose between two people after reviewing different information about each person, including whether or not they had a food restriction. As predicted, participants were significantly more likely to avoid the restricted individual, regardless of the reason for the restriction (i.e., peanut allergy, lactose intolerant, gluten intolerant), with only 41.5% of people selecting the person with a food restriction to partner with ($z = -2.88$, $p = .004$).

When we eat with others, we pursue multiple goals, from reducing hunger, meeting nutritional needs, and managing social relationships. The studies reported here demonstrate how pursuing a health goal (i.e., navigating a food restriction when eating) can harm social-relationship goals, identifying food restriction as a contributing factor to loneliness. Because food consumption is inherently social,
people who are unable to participate in the meal also, to some extent, are unable to participate in the social bond. With the knowledge that those with actual or imposed food restrictions feel lonelier, this work points to the theoretical connection between food consumption and social bonding.

SESSION OVERVIEW

In the last decade, behavioral researchers have faced increasing pressure to improve the methodology of data collection and analysis. A large survey documented the prevalence of research practices that are now considered “questionable” (e.g., stopping data collection when the desired results reached significance, John, Loewenstein, and Prelec, 2012). Similarly, several replication failures increased researchers’ awareness of publication bias, file drawer effects, and other forms of selective reporting that can increase the prevalence of false positive findings in the literature (Ioannidis, 2005). A new wave of methodological research emerged, that revived old warnings (e.g., about too small sample sizes, Cohen, 1992) and proposed new standards for summarizing results (e.g., internal meta-analysis, McShane & Böckenholt, 2017) and new methods to assess the evidential value of a set of results (p-curve, Simonsohn, Nelson, and Simmons, 2014). Has consumer research become wiser as a result? How can it improve its methods?

The four papers in this session present new descriptive and normative insights into the state of the methodology of empirical consumer research. Nelson, Gonzalez, O’Donnell, and Perfecto will present a p-curve analysis of more than 400 articles in social psychology. This will yield insights into the robustness of phenomena that consumer researchers often build upon. Vosgerau, Simonsohn, Nelson, and Simmons argue that the validity of internal meta-analyses relies on assumptions (e.g., complete absence of selective reporting) that are often unrealistic. As a result, they show that relying on internal meta-analysis to establish the robustness of an effect can greatly inflate, rather than reduce, the rate of false positives. Roos and Paolacci leverage the transparency of online samples to investigate the extent to which monetary considerations are a substantial constraint to researchers’ sampling decisions. They conducted an analysis of the MTurk study population before and after Amazon raised their commissions, and a coupon field experiment with researchers on Prolific. Results indicate that alleviating financial constraints would result in more studies and larger samples. Krefeld-Schwalb and Scheibehenne illustrate how selective reporting and statistical power in published consumer research has developed over time. By analyzing more than 900 articles in consumer research from 2011 to 2018, they found evidence that selective reporting has decreased. Together with an increase in sample size and decrease in effect size, these results suggest that the consumer research literature suffers less from false positive and false negative findings than it did in the past.

Altogether, these four papers contribute to our understanding of how individual consumer researchers and the field as-a-whole have navigated the methodological turmoil of the last few years and suggest ways to further strengthen our experimental research practices. We hope this session will trigger further interest in making consumer research wiser by improving its methodological practices.

Using P-Curve to Assess Evidentiary Value from 10 Years of Published Literature

EXTENDED ABSTRACT

P-curve is a tool that allows researchers to evaluate the evidentiary value in a given set of studies. The logic of p-curve is straightforward: because p-values are a conditional probability of observing a set of data (or data more extreme than what is observed) given that a null hypothesis is true (i.e. no effect), we know what the distribution of p-values should look like in the presence or absence of true effects.

If the null hypothesis is true, p-values will be uniformly distributed and show a flat line distribution with each value between 0 and 1 being equally likely. On the other hand, however, if an effect is true and the null hypothesis should be rejected, p-values should be strongly right-skewed with a spike at p approaching 0. The steepness of the curve is related to statistical power, with less power being associated with a flatter curve. This distribution of p-values will always occur when an effect is true, because if an effect truly does exist, the likelihood of finding large p-values is extremely small, and the bulk of p-values associated with statistical tests for a true effect will approach 0.

Finally, given the prevalence of p-hacking in published findings, p-curve is also a useful tool for identifying when p-hacking is likely present in a set of results. Because researchers are incentivized to report statistical tests with p-values at least below .05, if p-hacking is present in a set of studies, the distribution of p-values will be left-skewed with a spike approaching .05.

The simple logic of p-curve, the relationship between p-curve and statistical power, and the known distribution of p-values makes p-curve a powerful tool for researchers to assess how likely a set of studies (as in a paper, a journal, or a given research topic) are to contain evidentiary value for a true effect, and can be an important lodestar for researchers who are beginning to approach published findings at all levels.

To date, however, there does not yet exist a comprehensive database of p-values and there are few p-curves that cover a broad swathe of the literature. Indeed, while p-curving a literature is straightforward, it is an effortful process. Developing a p-curve disclosure table requires, at a minimum, reading a paper and reporting the research-
ers’ hypothesis (with quotes from the paper), the study design, the key statistical result, statistical tests, and text from the paper verifying these elements. Although arduous, collecting this information is crucial for allowing authors of p-curved papers to easily assess the accuracy of the p-curve. In our paper, we are attempting to reduce these high startup costs associated with developing a large-scale p-curve database by systematically p-curving a decade’s worth of findings in Section I of the Journal of Personality and Social Psychology (JPSP). We are also coding data beyond a typical p-curve disclosure table, such as keywords, whether the study excludes participants, specific experimental manipulations, whether the study tests mediation, and whether results are reported with and without covariates, in order to facilitate further metascientific analyses. We chose Section I of JPSP because it focuses on studies related to Attitudes and Social Cognition, contains the bulk of experiments in the journal, and is of the most direct relevance to Consumer Behavior researchers.

We have undertaken this endeavor as a means of developing a starting point for researchers who are interested in assessing the evidentiary value in a broad cross-section of psychological research that is relevant to scholars in marketing, management, social psychology, and many other behavioral fields. This p-curve database includes over 400 papers, each of which has been randomly assigned to be p-curved by two independent coders. The breadth of papers we have reviewed will allow researchers to assess entire streams of research within a given topic, evaluate trends in evidentiary value over time, assess whether specific manipulations or statistical results are associated with more or less evidentiary value, and so on. This will not only help get a sense of different literatures’ reliability, but also help researchers developing new ideas decide which areas may be the most fruitful for building upon.

The development of this database is still ongoing, but the initial set of 10 years’ worth of papers will be completed in Summer 2019. We plan to present a set of our most interesting, and consumer relevant findings from this database. We will also share the p-curve database as a public resource for consumer behavior researchers interested in evaluating the published research within JPSP.

99% Impossible: A Valid, or Falsifiable, Internal Meta-Analysis

EXTENDED ABSTRACT

Internal meta-analysis involves statistically aggregating all studies reported in a paper, usually to examine whether the overall effect is statistically significant. Internal meta-analysis increases statistical power, potentially encouraging researchers to report more of their studies, particularly those that did not yield conventional levels of significance. These purported advantages – more statistical power and less “file-drawer” – have made internal meta-analysis popular.

We propose that internal meta-analyses are likely to have unintended and potentially catastrophic consequences for the credibility of published findings. The validity of internal meta-analysis hinges on the assumption that none of the analyzed findings were affected by selective reporting; the method is valid only if one analysis were conducted on each study, and only if every study was included in the internal meta-analysis.

We worry that some researchers may believe that the selective reporting of favorable analyses is immoral, a malevolent form of dishonesty. By this logic, saying that selective reporting is almost inevitable is like saying that almost all researchers are bad people. We believe that selective reporting of favorable analyses and studies is not immoral, but in most cases the inevitable consequence of (moral) human beings’ tendency to interpret ambiguous information in ways that are consistent with their desires and beliefs (Kunda, 1990; Vazire, 2015).

To appreciate the near inevitability of this, consider what it would take to not do it. Researchers would either have to be indifferent to the outcome of their studies, or they would have to perfectly plan out in advance how many and which studies to run, which measures to analyze, how to score the measures, what sample sizes to use, which covariates to include, how exactly to deal with outliers or inattentive participants, etc. Motivated researchers who do not perfectly plan out their entire research project in advance will have to make ex post decisions about which studies to run, how to measure variables, which analyses use. And, because they are invested in the research project, they will make those decisions in ways that benefit them rather than in ways that harm them. Indeed, in the presence of desire and in the absence of perfect planning, some amount of selective reporting is virtually inevitable.

We show with simulations that small amounts of selective reporting can have dramatic consequences for internal meta-analyses. For example, the minimal selective reporting that inflates an individual study’s false-positive rate to just 8% will inflate the false-positive rate of a 10-study internal meta-analysis to 82%!

Imagine that researchers only conduct internal meta-analyses on sets of studies that were individually pre-registered, so there is no p-hacking at all. Even under these exceptional circumstances, internal meta-analysis would be invalid if the decision about which studies to include in the meta-analysis was at all influenced by that study’s results. If a researcher studying a false hypothesis needed 5 (out of 10) individually significant studies to successfully publish her result, she would have a one in 451,398 chance of succeeding. If the same researcher merely needed a significant meta-analysis of the best 5 out of 10 studies, she would have a 146,795 in 451,398 chance (or 32.5%) of succeeding. Ironically, internal meta-analysis exacerbates the consequences of the file-drawer problem, rather than alleviating it.

Finally, false-positive internal meta-analyses are prohibitively difficult to falsify, because if the original studies are distorted by selective reporting, the combination of original and replication studies will also be distorted by it. Using the previous example of a false-positive 10-study internal meta-analysis showing an effect, we proceeded to add 10 studies drawn under the null, re-running the meta-analyses now with 20 studies each (10 original and 10 replication studies). When all ten new replications had the same sample size as the original, 47% of false-positive internal meta-analyses remained significant. When all ten replications had 2.5 times the original sample size, still 30% of internal meta-analysis remained significant. Keep in mind that all of this assumes something extremely optimistic and unrealistic – that replicators could afford (or would bother) to replicate every single study in a meta-analysis and that others would judge all of those replication attempts to be of sufficient quality. Absent this wild assumption, we are left with the possibility that one cannot ever realistically attempt to falsify a false-positive internal meta-analysis.

Concluding, internal meta-analyses are valid only if (1) they exclusively contain studies that were properly pre-registered, (2) those pre-registrations were perfectly followed, and (3) the decision of whether to include a given study in an internal meta-analysis is made before any of those studies are run. These conditions are typically met in many-lab replication efforts, where the set of studies to be run is predetermined, and the exact design of each study is pre-determined also (see e.g., Alogna et al., 2014; Ebersole et al., 2016; Hag-
Outside many-lab replication efforts, we recommend to never draw inferences about the existence of an effect from internal meta-analyses. We don’t believe in the robustness of anchoring effects or motivated reasoning or preference projection because their findings have been meta-analyzed; we believe in them because the studies supporting them are well designed and because exact replications of these effects have been overwhelmingly successful. Scientific knowledge advances one replicable study at a time.

The Price of Behavioral Research

EXTENDED ABSTRACT

Experimental studies conducted on samples of human participants generate the bulk of evidence that drives behavioral consumer research forward. By collecting more evidence, whether through additional studies or larger samples, consumer researchers can measure behavior and test theories with greater precision. However, collecting evidence carries a monetary cost, and thus often entails a significant investment of scarce resources. How do researchers trade off monetary and scientific considerations? Two parallel phenomena make this long-standing question both pressing and answerable. First, the low replicability rate of findings in the behavioral sciences has revived old concerns about insufficient statistical power (e.g., Cohen 1992; Fraley and Vazire 2014; Maxwell 2004). It is important to understand whether sampling practices are bounded by financial constraints. Second, data collection in consumer research is moving away from physical laboratories in favor of online labor markets such as Amazon MTurk and Prolific (Goodman and Paolacci 2017). This removes many of the fixed costs of data collection, and thus make sampling decisions more dependent on the marginal cost of collecting additional observations. Moreover, the transparency of these marketplaces makes it possible to study researchers’ behavior with greater precision.

Normatively, how should researchers’ decisions about evidence to collect respond to the price of such evidence? The prescription of standard power analysis is straightforward. Sample sizes should be based on expected error rates and effect sizes, with no consideration for monetary costs. If the prescribed sample size happens to be compatible with the researcher’s budget, then the study can be conducted. Otherwise, the study is not supposed to be carried out. In other words, a different price should normatively lead to conducting a different number of studies, but not to collecting differently sized samples. We investigated these possible patterns in two separate studies on two major suppliers of online participants.

In the first study, we analyzed whether researchers responded to Amazon’s decision to raise the MTurk commissions in July 2015—factually increasing the price of data collection by 27%—by conducting fewer studies. Crawling data via the MTurk Tracker (Difallah et al. 2015), we analyzed surveys posted on MTurk in the two months before and after the price increase. We sought to measure the effect of the price increase on researchers who were already MTurk users. Hence, the analysis only considers activity among requesters who posted at least one survey or survey-based experiment on MTurk in the two months before the increase. The 2,292 requesters meeting these criteria posted 11,689 surveys during this four-month period.

We conducted a non-parametric change point analysis (Matte-son and James 2014) on four quantities: the total number of surveys posted, the number of unique requesters associated with those surveys (some requesters post more than one survey per day), the average payment per survey (not the hourly rate), and the maximum time participants were given to complete their surveys. The algorithm identified two change points—June 27 (less than a week after the new prices were announced, p = .014) and July 21 (the day before the price increase, p < .001). These change points partition the data into three periods—pre-announcement, post-announcement, and post-increase.

To summarize results, prior to the announcement, an average of 82.5 (SE 5.1) requesters posted 135.3 (SE 20.7) surveys each day, offering an average reward of $0.60 (SE $0.02). After the announcement, the number of requesters and surveys did not meaningfully change, though the average reward increased by more than half to $0.96 (SE $0.06) per survey and grew more volatile. Most importantly, in the two months following the price increase, while average rewards fell to a value closer to the pre-announcement average, $0.72 (SE $0.02) per survey, the daily number of surveys and active requesters dropped by about half, to 43.4 (SE 2.4) requesters and 62.0 (SE 3.6) surveys. The maximum time allotted to surveys did not meaningfully vary over the four months. In sum, these results suggest that researchers reacted to the price increase by conducting fewer studies.

Importantly, the MTurk Tracker does not allow observing sample sizes. To understand whether sampling prices affect sample sizes, we conducted a preregistered field experiment on the entire population of researchers registered with Prolific who reside in the Netherlands (N = 167). In a between-participants design, researchers were either assigned or not to receiving a 15% discount off the total cost of their next study. Contrary to the prescription of standard power analysis, we found that researchers receiving the discount collected significantly larger samples (M = 290 vs. 116, medians = 240 vs. 70, Wilcoxon rank sum test p = .0086). Many compatible explanations exist for this effect: the discount may have affected sample sizes by influencing researchers’ choice of which study to run next, prompting a significant alteration in the design or sample size of an already-planned study, or increasing the budget allocated to a study. Regardless of the mechanism, a short-term decrease in the cost of collecting evidence led researchers to accumulate far more evidence than their counterparts in the control.

The results from our second study suggest that sample sizes are affected by financial constraints, even in relatively cost-effective research environments. Critically, underpowered research has many causes, including underused or misinformed power analysis, and failing to recognize questionable research practices as such (e.g., Simmons, Nelson, and Simonsohn 2011). However, these results suggest that above and beyond these components, researchers might collect smaller sample sizes than they would if they were less financially constrained.

Taken together, the findings from these two studies illustrate how the production of evidence in the behavioral sciences does not depend exclusively on scientific considerations. On the contrary, researchers respond to changes in the opportunity costs of empirical studies by adjusting their sample sizes, and by conducting more or fewer studies. We will discuss the statistical, design, and institutional solutions available to researchers to trade off financial and scientific considerations more efficiently.

Tighter Nets for Smaller Fishes: Mapping the Development of Statistical Practices in Consumer Research Between 2011 and 2018

EXTENDED ABSTRACT

The replicability of empirical findings is a core aspect of (consumer) research (Popper, 1959). Recently, the need to improve the replicability of published findings has been called for across the
empirical social sciences, including consumer research (e.g. Ioannidis 2005). Towards this goal, several major journals have revised and strengthened their publishing policies, focusing more on the transparency and reproducibility of published research (e.g. Inman, Campbell, Kirmani, & Price, 2018; Pechmann, 2014). However, despite the awareness for the topic in the field, up to date, there has been no comprehensive evaluation of the replicability of published consumer research, nor how it developed or perhaps even improved in recent time. The present study provides a systematic review of the replicability of published consumer research. In particular, we investigated whether the replicability of consumer research has increased in recent years. Given the increasing discussion around the topic, such an improvement seems plausible.

The replicability of a statistical test depends on its statistical power which in turn depends on sample size and effect size. Once both are known, one can determine a distribution of p-values, i.e. the probability of observing different p-values. However, the effect size reported in published studies might not necessarily represent the true effect size of the statistical test, due to selective reporting and publishing of significant over non-significant findings (Duval & Tweedie, 2000; Egger, Smith, Schneider, & Minder, 2015; Ferguson & Brannick, 2012; Franco, Malhotra, & Simonovits, 2014; Rosenthal, 1979; Sterling, 1959). Together with other ways of selective reporting (Gelman & Loken, 2014), this increases the risk of overestimating the power of published studies and can increase the number of false positive findings in the literature and hence decrease the replicability of published findings.

One way to investigate the amount of selective reporting in published research is the analysis of the distribution of reported p-values (Simonsohn, Nelson, & Simmons, 2014). With any non-zero effect, the p-value distribution is right skewed, smaller p-values are more likely observed in a statistical test than higher p-values. If the effect size is zero, the distribution of p-values is uniform. In contrast, selective reporting, given that the effect size is zero, will produce a p-value distribution that is left skewed, below the level of significance. Thus, selective reporting distorts the distribution of p-values by increasing the proportion of values below the level of significance relative to the proportion that would be expected based on the observed statistical power.

Given the recent discussions in the social sciences on how to improve methodological and statistical practices in the field, we expected to observe an increase in the statistical power in the consumer research literature in the time period from 2011 to 2018. We further expected that publication bias decreased across that period. To test these hypotheses we focused on two commonly applied statistical tests in empirical consumer research, namely F-tests (i.e. analysis of variance) and t-tests. For both tests we analyzed the reported statistics across 971 articles published in the Journal of Consumer Research, the Journal of Consumer Psychology and the Journal of Marketing during that time period.

We first analyzed changes in the statistical post-hoc power over time. Given that sample sizes increased significantly from an average of 128 subjects in 2011 to on average 204 subjects in 2018, but effect sizes decreased across the same period from a median of .30 in 2011 to .22 in 2018, the average post-hoc power did not change. We further found no significant difference between the journals for any of the dependent variables.

Second, we tested whether the distribution of reported p-values changed in accordance with the distribution expected based on the reported power. On that account we analyzed the proportion of significant p-values in the articles as reported and expected based on the average reported power over time. We further separately investigated the development of p-values below and above a level of significance \( \alpha = .005 \) as proposed by Benjamin et al. (2017).

Despite that there was no decrease in statistical power over time, the reported proportion of significant findings, \( p < .05 \), decreased. However, the frequency of p-values in the intervals above and below the stricter level significance developed differently. P-values above the stricter level of significance, \(.005 < p < .05\), decreased. Across all years and journals, p-values in this interval, \(.005 < p < .05\), were yet more often reported than expected based on the power distribution. To the contrary, p-values below the stricter level of significance, \( p < .005 \), were less often reported than expected. Over time, however, the discrepancy of the expected and observed proportions of p-values has decreased.

One possible explanation for these results is that the increase in sample size over time indicate increased awareness for the need of higher powered studies. As a consequence, the decrease in effect size over time can be interpreted as a more exact estimation of the true sample sizes (Loken & Gelman, 2017; Greenwald, Gonzalez, Harris, & Guthrie, 1996; Lane & Dunlap, 1978; Maxwell, 2004; Schmidt, 1992). Moreover, the reduction in discrepancy of the expected and the observed proportions indicates that selective reporting of significant findings in consumer research has decreased over time.

SESSION OVERVIEW
New technologies that allow consumers convenient and interactive ways to learn about and purchase products are changing the landscape of consumer behavior. The aim of this session is to showcase how different types of new technologies are being incorporated into marketing and identify the strengths and limitations of such technologies. We will examine how four different types of technological advancements (e.g., augmented reality, virtual reality, voice interfaces, and virtual assistants) affect different stages of the decision-making process: information seeking, product evaluation, consumption choice, and method of purchase.

The session will open with a paper that focuses on technology in product presentation. Park and Huang will discuss the effects of augmented reality on information seeking and product evaluation. Augmented reality technology expands the physical world by superimposing digital data onto physical objects. Across three studies, including an in-lab study in which participants use iPads and QR codes to obtain information about food products, Park and Huang identify augmented reality technology as most effective when it contains both visual elements and interactive information. In the second paper, Jun, Chung, and Johar offer insight into the limitations of virtual reality—in which consumers immersively experience a world outside of reality—in encouraging future consumption. Across a field study and lab studies, they find that providing stimulation through virtual reality experiences may decrease consumers’ preference for similar stimulating activities if those consumers are highly sensation-seeking. Thus, heterogeneity in consumers moderates the impact of virtual reality in subsequent choice.

The final two papers of the session explore consumers’ interaction with virtual assistants and voice interfaces and provide implications for completing the product purchase. Voice interfaces allow users to interact with a system through speech and auditory responses. Voice interfaces therefore can both receive from and provide information to users, including information about search results and product recommendations. The third paper, by Mariadassou, Bechler, and Levav shows that auditory recommendations are adopted more than visual recommendations, highlighting the potential impact for voice assistants in consumers’ ultimate product choices. Notably, the effect persists regardless of the type of voice used in auditory recommendations: human voices or automated voices. Last, across three field experiments in which participants interact with a virtual assistant, Schroeder and Schroeder show that consumers are more likely to reveal personal information to a machine when they speak rather than type to the machine. This personal information includes search history, purchase history, and credit card information. These results provide insights into consumers’ likelihood of following through on purchase intentions as well as implications for cybersecurity.

Combined, these four papers suggest that the effects of new technologies in marketing are nuanced, with each technology possessing unique strengths in assisting consumers with evaluating, choosing, and purchasing products. The papers draw from literature on sensory seeking, stimulation, anthropomorphism, cognitive psychology, and modalities to explore underlying psychological processes behind human interaction with technology. We believe that this session will attract a diverse audience and provide fruitful discussion for innovative and timely research regarding technology in consumer behavior.

Augmented Reality Dissected: Decoupling the Visual and Interactive Elements of AR in Encouraging Consumers to Read Food Reviews

EXTENDED ABSTRACT
Augmented Reality technology overlays digital data onto physical objects in real-time and provides an interactive experience. With its increased affordability, AR has become one of the most exciting new tools for marketing and has been adopted in consumer-relevant domains such as AR food menus (e.g., Kayaq). However, little work has explored how consumers experience this new technology and its impact on consumer preference.

Specifically, recent research shows that AR has two key elements—rich visual prompts and interactivity when calling out information (Azuma et al. 2001; Iavornik 2016). Visual annotations of AR, more technically known as “augmentation,” are its most salient and well-developed feature (Billinghurst and Kato 2002; Fitzgerald et al. 2013). Moreover, interactivity is one of the most established concepts related to digital consumer technologies (Hoffman and Novak 1996), soliciting a strong reaction from users through immersion and enjoyment (Hoffman and Novak 2009).

In this research, we tease apart these two critical dimensions of AR—visual and interactivity—and test how these dimensions affect consumers’ desire to read food reviews and the type of food information they access. In three studies including a lab experiment with 15 AR codes on 15 snack items, we manipulated the visual and interactive features respectively, and found that people were more likely to interact with food reviews (e.g., scan a code, click a button to load information) when the food was visually present, underscoring the central role that visual prompts played. Interestingly, presenting food reviews in AR boosted the browsing of unhealthy (vs. healthy) food.

Study 1 (N = 605) tested the effect of visual and interactive elements in AR on the likelihood of exploring snack information and subsequent liking toward the snacks with a 3 (information format: visual-and-interactive combined vs. interactive-only vs. visual-only; between-subjects) x 2 (food type: healthy vs. unhealthy; within-subjects) mixed design. All participants were asked to read information...
about 10 snack options (five healthy and five unhealthy) and received basic text information—snack name, ingredients—for the snacks, all of which were displayed on a page in a menu board-like fashion. In the visual-and-interactive combined condition, participants saw the product image (visual) and the “customer reviews” button, which displayed reviews upon clicking (i.e., requiring interaction from the users). In the interactive-only condition, the “customer reviews” button was present without the snack images. In the visual-only condition, the images were present, but all review text was displayed as the default without the button. After exploring the snacks, participants completed the rating questionnaire.

Among the conditions where participants needed to “click/interact” to load information (i.e., the combined and interactive-only conditions), we observed the hypothesized format x food type interaction, such that participants clicked more unhealthy (vs. healthy) snacks when the visual was present ($M_{combined} = 2.64$) than when absent ($M_{interactive-only} = 2.09, p = .001$); those in the visual-only condition did not click to load information, thus their clicking behavior was zero. Importantly, those in the visual-and-interactive combined condition rated unhealthy snacks more favorably ($M_{unhealthy} = 4.70$ vs. $M_{healthy} = 4.35, p = .002$), whereas such preference toward unhealthy snacks did not occur in conditions where only the visual or the interaction was present.

Study 2 ($N = 607$) examined whether increased browsing and liking of unhealthy snack could translate to food domain as well. Participants imagined exploring digital menu boards at the TGI Friday’s restaurant and reviewed 10 entrées (five healthy and five unhealthy). As in Study 1, the information format varied across conditions (visual-and-interactive combined vs. interactive-only vs. visual-only). Consistently, participants were more likely to seek customer reviews of unhealthy food when the visual was present ($M_{combined} = 2.39$) than when absent ($M_{interaction-only} = 2.02, p = .02$); those in the visual-only condition did not need to click/seek information. We again observed that participants rated the unhealthy entrées significantly higher in the combined format ($M_{combined} = 4.44$) than in the other two formats ($M_{interactive-only} = 4.29, M_{visual-only} = 4.32$), although this difference was only directionally significant, $p = .16$. Finally, participants were more likely to choose an unhealthy entrée when it was visually stimulating ($M_{combined} = 52.2\%$) than when not ($M_{interaction-only} = 44.9\%, p = .07$).

Study 3 ($N = 442$) tested the AR effect in the lab, where participants could physically examine products and use a device to scan the codes to load more product information. We manipulated the visual and interactivity of AR across three conditions and tested whether the effect was unique to social reviews by adding other types of information, resulting in a 3 (format: visual-and-interactive combined vs. interactive-only vs. visual-only; between-subjects) x 3 (food: healthy vs. neutral vs. unhealthy; within-subjects) design. In the visual-and-interactive combined condition, 15 snacks (five healthy, five neutral, five unhealthy) were laid out on the table, each snack with a unique QR code to be scanned with an iPad for additional information. In the interactive-only condition, participants first viewed snacks without the QR codes in one room and moved to another room, where they interacted with the QR codes without the food items (visuals) present. In the visual-only condition, we removed the interactivity aspect of QR codes, providing food information (preloaded onto all iPads) without scanning.

We found consistent results; when the QR codes provided social information (i.e., customer reviews), participants in the combined condition were more likely to explore unhealthy snacks than those in the interactive-only condition ($M_{combined} = 46.3\%$ vs. $M_{interactive-only} = 38.6\%, p = .036$). Furthermore, participants in the combined condition rated unhealthy snacks higher ($M_{combined} = 4.59$) compared to when only one of the two was present ($M_{interactive-only} = 4.17, M_{visual-only} = 4.42, p = .06$). Importantly, these effects were only present when the augmented information was social (vs. nutrition, exercise).

Together, we find that both the type of physical products (e.g., unhealthy vs. healthy food) and the delivery of augmented information (e.g., visual prompts) are critical in determining consumers’ likelihood of using AR and their subsequent preference of the product.

### When Virtual Reality Backfires on Reality: VR Reduces High Sensation Seekers’ Desire for Stimulation

**EXTENDED ABSTRACT**

Virtual Reality is a “set of technologies that enable people to immersively experience a world beyond reality” (Berg and Vance 2016), allowing users to feel “present” in another world and businesses to enhance brand engagement (Bailenson 2018). Six Flags offers VR roller coasters in partnership with Samsung, and Warner Bros. released a VR trailer for *Conjuring 2*, in which viewers investigate a paranormal activity in a haunted house alongside the protagonists. Focusing on such stimulating virtual experiences, we find that contrary to marketers’ expectations that VR will invite future consumption, using VR can backfire and decrease consumers’ desire for more.

The need for stimulation is inherent in humans (Leuba 1955) and consumption activities can satisfy this need. Consumers try new brands, engage in risky activities like skydiving, and add variety to their choices to achieve stimulation (Howard and Sheth 1969). Particularly, those with higher need for sensation (i.e., high sensation seekers) dislike predictable or repeated experiences because they experience the same stimulus object more intensely than low sensation seekers (Raju 1980; Berlyne 1960). For example, they generate more curiosity-related thoughts while watching an ad (Pearson 1970), and show greater inquisitiveness (e.g., posing questions, detecting more perceptual cues) that go beyond the objects they see (Wright 1973). We predict that highly sensation-seeking consumers will experience the virtual stimulus intensely in order to satisfy their need for sensation in VR, reducing their subsequent desire for similar, stimulating consumption experiences in physical reality.

Two pilot tests justify our focus on stimulating virtual experiences, by revealing that people believe an experience delivered through the VR technology is more stimulating than the same experience delivered without VR, and that most of the publicly available VR contents are indeed stimulating. 305 participants indicated how much stimulation various experiential mediums (e.g., TV, radio, VR) elicit. As predicted, people thought VR was the most stimulating medium of vicarious experiencing, compared to watching television ($M = 65.4, p < .05$), imagining ($M = 49.0, p < .001$), listing to the radio ($M = 43.6, p < .001$), or reading about an event ($M = 39.4, p < .001$). Next, a content-analysis of 150 publicly available VR videos (i.e., Youtube “Virtual Reality” channel) revealed that 77% of the videos featured highly stimulating outdoor activities (e.g., skydiving). Even the remaining 23% on indoor activities used highly stimulating contexts (e.g., haunted house).

Study 1 revealed that high sensation seekers report attenuated desire for sensation after using VR. The study took place in a South Korean “VR theme park”, a commercial VR entertainment complex. All customers ($N=283$) to the theme park were considered high sensation seekers. Customers indicated their desire for stimulation by first indicating their preference for various exciting consumption activities (e.g., bungee jumping compared to a massage), and then actually choosing between a ‘mysterious’ candy of unknown taste
Recommendation Modality Affects Choice: Auditory Recommendations are Followed More Than Visual

EXTENDED ABSTRACT

Voice interfaces, such as the Amazon Echo, Google Home, and Apple HomePod, are currently among the world’s fastest-growing technology segments (Molla 2018). They are used for online search, information, shopping, and — increasingly — recommendations. Popular sentiment suggests that voice technology is currently not achieving its full potential and is simply another tool through which consumers can receive information. This idea assumes that consumers weight information identically, regardless of the modality through which they receive information. Conversely, our research suggests that modality does matter: technology can create different physical experiences despite identical information, which leads to different behavioral consequences. In this research, we find that consumers are more likely to follow recommendations they hear rather than recommendations they read.

One may have predicted the opposite result. In prior research, expression modality has been shown to influence the content of a message or choice (Klesse, Levav, and Goukens 2015; Berger and Iyengar 2013). Compared to oral communication, written communication leads people to mention more interesting products, partly because communicators have more time to formulate what they say (Berger and Iyengar 2013). As such, one might expect a learned association such that consumers find written recommendations generally more persuasive than auditory recommendations. In fact, a pilot study in which participants were asked to recommend their favorite movie by either speaking or typing revealed that participants who typed their recommendations felt more persuasive ($M = 4.77$) than those who spoke ($M = 4.09$, $p < .001$).

Nevertheless, across 6 experiments (Total $N = 3,900$), we find the opposite: our results suggest that spoken recommendations are more persuasive. This finding is in line with other work regarding modality effects on recipients of communication. Prior research shows that speakers seem more competent, intelligent, thoughtful, and mentally capable than writers sharing identical information (Schroeder and Epley 2015; Schroeder, Kardas, and Epley 2017). Interestingly, we find that positive effects of auditory messages (compared to visual) extend beyond human voices to automated voices as well, as manifested in recipients’ likelihood of following the communicator’s recommendations.

Study 1 ($N = 379$) revealed this main effect. Study 1 used a 2 (modality: auditory vs. visual) × 2 (source: Google or non-Google) between-subjects design. Each participant either heard (auditory) or read (visual) a recommendation for one option in eight different product categories and then had to make a choice among three options in each category, one of which was the recommended option. Participants in the Google conditions were told to imagine that they were using either a Google Home or a Google search engine to find a recommendation, depending on if they were in the auditory or visual conditions, respectively. Participants in the non-Google conditions were simply told to imagine that they were looking for a recommendation. In the non-Google auditory condition, recommendations were spoken by a human voice. In the Google auditory condition, recommendations were spoken using text-to-speech software, in which the software employs a robotic-sounding voice to read aloud text.

Results from a logistic mixed-effects regression analysis revealed a main effect of modality ($b = 0.63$, $SE = 0.12$, $p < .001$) such that auditory recommendations were more likely to be adopted than visual recommendations. Importantly, there was no significant interaction between mode and source on the likelihood of following the recommendation ($p > .70$); nor did we find a main effect of the source ($p > .40$). The main effect of modality remained significant when analyzing the Google and non-Google data separately (Google: $b = 0.58$, $SE = 0.17$, $p < .001$; non-Google: $b = 0.69$, $SE = 0.19$, $p < .001$).

In Study 2, we replicated the effect of modality. Study 2 ($N = 724$) used a simplified design of 3 conditions: auditory-human voice, visual-typed, visual-handwritten. The purpose of the hand-
written condition was to humanize the recommender in the visual condition. We measured perceptions of the recommendation as coming from a human creator (adapted from Schroeder & Epley, 2016). Participants who heard recommendations spoken by a human were more likely to believe that the recommendations were created by a human than participants who read typed recommendations ($M_{auditory} = 6.35$ vs. $M_{typed} = 5.50, p < .001$). However, participants who heard recommendations were less likely to believe the recommendations came from a human than those who read recommendations handwritten by a human ($M_{auditory} = 6.88, p = 0.02$). Nonetheless, auditory recommendations were followed more than both typed ($b = 1.69, SE = 0.20, p < .001$) and handwritten recommendations ($b = 1.10, SE = 0.20, p < .001$), thus providing evidence against perceived humaneness of the recommender as a potential explanation for the effect.

Studies 3-6 replicated the main effect of modality using different stimuli and provided preliminary evidence that casts doubt on other mechanisms. In Study 3 (N=801), we manipulated the ease with which participants read or heard the recommendations by inserting blurriness or static into the recommendations; we found no interaction between ease and modality ($p > 0.10$), yet still found a main effect of auditory recommendations being adopted more than visual ($p = 0.04$). In Study 4 (N=599), we measured participants’ memories of the recommendations prior to asking them their choices and found no differences in memory across modalities ($p > 0.10$); the main effect of auditory remained significant ($p = 0.02$). In Study 5 (N=807), we manipulated the source of the recommendation to be an expert or novice but found no interaction with modality ($p > 0.80$); the main effect of auditory remained significant ($p = 0.01$). In Study 6 (N=590), we manipulated the time at which the recommendation was generated to test for perceived relevance of the recommendation; we found the main effect of auditory recommendations ($p < .001$) but no interaction ($p > 0.70$). Ultimately, there seems to be a fundamental difference in the modalities of hearing and reading that leads people to adopt auditory recommendations more than visual ones.

This research illustrates the importance of auditory mediums and has profound implications for developers of voice assistants, highlighting the impact of integrating auditory recommendations into such systems.

**Should I Give Siri my Credit Card? How Mode of Interaction Affects Willingness to Share Personal Information with Machines**

**EXTENDED ABSTRACT**

Every day, people make decisions about whether to share their personal information with machines, from entering a credit card number into a company’s website to allowing a phone to track one’s location. How do people decide whether to share information? We explore how the modality by which people interact with machines can affect sharing behavior. Specifically, we consider two criteria—whether the user talks or types to the machine (i.e., expression modality) and whether the machine talks or types back (i.e., response modality).

Based on prior research, we expected that both expression and response modality could influence sharing behavior. First, expression modality has been previously shown to influence self-control behavior (Klesse, Levav, and Goukens 2015; MacLeod 1991; Paus et al. 1993). For instance, verbally expressing one’s choice (i.e., speaking) increases heuristic decision-making and indulgence, thereby reducing self-control, compared to physically expressing one’s choice (e.g., button pressing, pointing, typing) for identical self-control dilemmas (Klesse et al. 2015). If speaking activates a more heuristic-driven mindset than other forms of engagement, then perhaps people will be quicker to share information—not thinking as carefully about whether or not it is a wise decision—when they speak to a machine.

Second, response modality has been shown to influence anthropomorphism. A machine that can create speech should be judged as more human-like than a machine that creates text. In one set of experiments, participants who read a statement that had been created by either a human or machine were less likely to believe the text had been written by a human than those who heard the same text spoken aloud (Schroeder and Epley 2016). Furthermore, self-driving cars with human voices seem more human-like and are trusted more by users (Waytz, Heafner, and Epley 2014).

To examine the effect of modality on sharing behavior, we conducted three field experiments in San Francisco and Chicago. All experiments used a similar procedure: Individuals were recruited to ostensibly test a new virtual assistant application in exchange for a food item. To do so, participants conversed with the application via different randomly assigned modalities (e.g., talking, typing) for about 5 minutes. They subsequently reported their evaluations of the virtual assistant and what information they would be willing to share with it.

We measured anthropomorphism in all studies (adapted from Bastian and Haslam 2010, e.g., “How intelligent did it seem?”; “How responsive did it seem?”) and social engagement in Exp’s. 2 and 3 (e.g., “I felt engaged”, “I felt like I was interacting with a real person”). We also measured how much participants “typically trust new technology” and “are familiar with using virtual assistants” and their demographic information. To examine our key hypothesis about sharing behavior, we asked participants whether they would be willing to share 12 different types of information (e.g., calendar, contacts, location, credit card, internet search history) with the application.

To select a virtual assistant, we examined all possible applications that 1) could talk or type, 2) could respond to voice or text, 3) would be relatively unfamiliar to participants so they would not have pre-existing opinions about it, and 4) seemed relatively humanlike (based on prior Turing Test competitions). The application that fit our needs was “Cleverbot,” which uses algorithms to have realistic conversations. Cleverbot has held over 200 million conversations since it went online in 1997. In the national 2011 Turing Test competition, Cleverbot was judged to be 59.3% human, compared to the rating of 63.3% human achieved by human participants.

Experiment 1 recruited 416 respondents in one of eight conditions: 2 (user’s expression modality: talk, type) × 2 (machine’s response modality: talk, type) × 2 (machine’s gender: male, female). We manipulated the machine’s gender because some prior research indicates that people apply human gender stereotypes to machines (Nass, Moon, and Green 1997). Results revealed the predicted main effect of expression modality, $F(1, 402)=6.12, p=.014$, such that users who talked to Cleverbot shared more information than users who texted. This effect remained when controlling for comfort with new technology, familiarity with virtual assistants, user age and gender, and the survey evaluations, $R^2=.063, p<.05$. However, there were no effects of response modality, the machine’s gender, or interactions between conditions, $F<1$. Surprisingly, there were also no effects of any condition on anthropomorphism, $p>.065$.

Experiment 2 (N=110) used a simplified design of just two experimental conditions—user typing or talking—to conduct a replication of Experiment 1. Supporting the findings from Experiment 1, there was an effect of expression-modality on sharing behavior, $t(106)=3.42, p=.001$, even when controlling for user demographics.
and survey evaluations. However, there were no effects on rated anthropomorphism or social engagement.

Finally, Experiment 3 (N=293) manipulated both expression and response modality (4 conditions). It revealed a weaker effect of expression modality than in prior experiments: non-significant although in the predicted direction: F(1, 290)=1.93, p=.166, and no effect of response mode or interaction, ps>.250. Across the three experiments in a meta-analysis, the aggregate effect of expression-modality was r=.320, p<.01.

These results raise many new questions for future research. First, why did we observe no effect of response modality? We suspect that a machine’s voice may only be humanizing when it contains reasonably human-like paralinguistic cues (e.g., intonation). As preliminary support, users reported that Cleverbot’s voice was not humanlike (below the scale midpoint). Second, how robust is the seemingly weak effect of expression modality, and would it apply to real decisions to share data? To test this, we are currently running two more pre-registered experiments in which participants actually decide whether or not to share their phone data with real virtual assistants installed on their phones.

Overall, despite the remaining questions, this work has the potential to shed light on key theoretical questions in psychology and human-computer interaction. Modern technology continues to integrate capabilities associated with artificial intelligence. How users interact with this technology can influence their likelihood of sharing their personal and sensitive information. Understanding these interactions is integral to guiding secure development and use.

SESSION OVERVIEW
Numbers are critical inputs in consumer decisions. Consumers evaluate products based on device specifications, average product ratings, promotions, and when responding to surveys on smartphones. How do consumers perceive and evaluate the numbers they encounter? And how does this process guide behavior?

This symposium’s objective is two-fold. The first objective is to glean a better understanding of how people process numerical information. Combined, the papers explore not only the processing itself, but also how framing and situational factors can influence this processing. The second objective is to explore the practical consequences of these novel theoretical contributions.

Pena-Marin and Isaac and Bechler, Levav, and Morris open the session by discussing the incorporation of numerical precision into judgment. Pena-Marin and Isaac find that numerical precision influences how consumers weight attributes when making decisions because precise numbers are associated with reduction. Whereas precise numbers carry greater weight when consumers prefer lower values of an attribute (e.g., a tablet’s price), less precise numbers (e.g., whole numbers) carry greater weight when consumers prefer higher values of an attribute (e.g., a tablet’s wireless range). Relatedly, Bechler, Levav, and Morris reveal that when consumers encounter whole-number average ratings (i.e., less precise averages) they perceive these average ratings to come from less variable distributions than non-whole-number average ratings—even when this is statistically unlikely. This error in perception is a product of the representativeness heuristic and can affect consumer choice because consumers typically reject outcomes that they see as more variable.

Isaac, Sevilla, and Bagchi and Kyung, Thomas, and Krishna conclude the session by discussing effects of framing the same numbers in different ways. Isaac, Sevilla, and Bagchi examine how the framing of equivalent numerical compensation information—as a high rate on a low gross amount (e.g., 10% on a $10,000 sale) or a low rate on a high gross amount (e.g., 1% on a $100,000 sale)—can affect its evaluation. They find that the former is evaluated more favorably because employees rely more on the commission rate since it is easier to evaluate. Relatedly, Kyung, Thomas, and Krishna examine how the framing of a scale can affect scale point (i.e., numerical) responses, revealing that scales oriented vertically can lower evaluations compared to scales oriented horizontally. This finding has large marketing and research implications, as horizontal numerical scales on survey platforms (e.g., Qualtrics) are sometimes automatically re-oriented to display vertically on mobile devices.

Combined, these four complete papers contribute to the fields of numerical cognition and consumer psychology in two ways. Theoretically, the session provides important answers to open questions about numerical processing. Practically, the session provides psychological insight into a wide array of instances in which we encounter numbers, including how consumers evaluate product attributes and mentally represent product ratings, how employees evaluate their compensation, and how people respond to surveys. We envision the questions posed and answered in this session will both further develop our understanding of numerical processing and spur innovative research in this influential area.

Placing Value on Place Value: Numerical Precision Influences the Weighting of Ascending versus Descending Attributes

EXTENDED ABSTRACT
When choosing from a product assortment, consumers often compare options on multiple product attributes (e.g., product weight, computing speed). More often than not, consumers may be forced to decide between products that are superior on different attributes. How do they make these tradeoffs? Research on information integration (e.g., Anderson 1981, 1982) suggests that consumers might assign a subjective value to each attribute and then weight these different attributes in some fashion to arrive at a product decision (e.g., by choosing the product with the highest importance-weighted utility).

We show that attribute weights are influenced by the level of precision of the numerical values that are used to describe the attributes themselves (e.g., 12.21 vs. 12). In particular, we find that consumers’ preference for numerical precision differs for ascending versus descending attributes. Consistent with prior research (e.g., Gunasti and Ross 2010), we define ascending attributes as those in which higher numbers indicate greater value (“the higher, the better”), whereas descending attributes are those in which lower numbers denote greater value (“the lower, the better”). When considering a tablet computer, for example, processor speed is an ascending attribute because consumers typically derive greater utility when the numerical values representing processor speed (e.g., GHz) increase. On the other hand, product weight is a descending attribute because consumers derive greater utility when the numerical values representing product weight (e.g., pounds) decrease.

Drawing on past research on attribute weighting (e.g., Huber, Payne and Puto 1982; attribute compatibility (e.g., Nagpal and Krishnamurthy 2007; Nowlis and Simonson 1997), and numerical cognition (e.g., Dehaene 2011; King and Janiszewski 2011), we hypothesize that consumers will weight descending attributes more [less] heavily in their decision making if attribute information is more [less] precise. As a result, consumers considering the same assortment may make different choices when the precision of attribute information is varied. We further propose that this effect manifests because consumers mentally associate precise numbers with the concept of reduction, which in turn heightens the accessibility and perceived importance of...
other reduction-oriented stimuli such as ascending attributes (that improve as their numerical value is reduced).

Four studies provide support for our theorizing. In study 1A, 233 students were successively shown four reduction-related images and four expansion-related images (randomized) and asked to choose the one number that “goes better” with the image from two options. The two numbers ranged from 11 to 99.99, with one relatively less precise number (i.e., whole numbers with no decimal points) and one relatively more precise number (i.e., numbers with two decimal points) in each choice set. Participants selected the more precise number in 57.2% of the cases in which they encountered a reduction-related image. In contrast, they chose the more precise number only 34.4% of the time when they encountered an expansion-related image; χ²(1) = 97.13, p < .001. Study 1B was an Implicit Association Test (IAT, Greenwald, McGhee, and Schwartz 1998) in which 177 students’ response latencies were compared when precise numbers were paired with reduction-related words (compatible) or with expansion-related words (incompatible). As expected, participants’ responses were faster in the block in which the two categories were compatible (M = 813.46 ms, SD = 561.77) than the block in which they were incompatible (M = 832.17, SD = 634.46), which suggests that the concepts are cognitively linked.

In study 2, 293 students imagined that they were shopping for a pair of new wireless headphones and were concerned about two attributes: product weight (i.e., descending) and wireless range (i.e., ascending). Subsequently, they were presented with a set of three typical values for each attribute that varied in terms of numerical precision (less vs. more) and asked to estimate the relative weighting they would place on each attribute (1 = completely rely on product weight, 7 = completely rely on wireless range). Irrespective of whether the ascending attribute had a higher or lower magnitude than the descending attribute, we observed a main effect of numerical precision such that participants relied relatively more on the ascending attribute (i.e., product weight) when numerical values were less precise versus more precise (M_less_precise = 4.83, SD = 1.30 vs. M_more_precise = 4.50, SD = 1.46; F(1, 289) = 4.19, p = .04).

In study 3, participants chose one out of four tablet computer options that were described using an ascending attribute (consumer ratings) and a descending attribute (price). The values of consumer ratings and price were cross so there was not a dominant option. We obtained a significant effect of numerical precision (Wald c²(1) = 8.37, p < .01) on choice. Participants were more likely to select one of the low-priced tablets in the high-precision condition (54.5%) versus the low-precision condition (40.2%). In contrast, participants were less likely to select one of the highly-rated tablets in the high-precision condition (45.5%) versus the low-precision condition (59.8%). We also created a reduction index (α = 93) that captured the extent to which participants associated the numbers used to describe the tablet with expansion/contraction, growth/reduction, increases/decreases, and addition/subtraction. Mediation analysis showed that when numerical precision and the reduction index were used to predict tablet choices, the effect of numerical precision was no longer significant (β = -0.48, SE = .29; t(194) = -1.65, p > .09). Instead, the reduction index (β = -2.4, SE = .14; t(194) = 2.06, p = .03) served as a significant predictor. When estimated using 10,000 bootstrapped samples, the indirect effect was found to be significant (β = .10, SE = .07), with the 95% confidence interval excluding zero (-.30 to -.01).

In sum, we contribute to research on numerical cognition that has previously shown that consumers infer quality (Schindler, Parsa, and Naipaul 2011), magnitude (Thomas, Simon, and Kadiyali 2010), and confidence (Welsh, Navarro, and Begg 2011) from numerical precision. We provide the first demonstration that numerical precision is also associated with the concept of reduction and that this association can systematically affect how consumers weight attributes and make decisions.

**Consumers Perceive That Whole-Number Average Ratings Reflect Less Variable Distributions**

**EXTENDED ABSTRACT**

Consumers routinely consult average product ratings to gather information about a product’s quality (e.g., de Langhe, Fernbach, and Lichtenstein 2016). In addition to quality information, average ratings can also evoke beliefs about their distribution. The present research examines how the decimals associated with an average rating can influence consumers’ perceptions of the variability in the ratings that make up that average. Specifically, we test whether “whole-number” average ratings (e.g., 4.00, 4.0, or 4 out of 5 stars) are perceived to have less dispersion than “non-whole-number” average ratings (e.g., 4.01, 4.10, or 4.11 out of 5 stars). Because consumers prefer certainty to uncertainty (i.e., less variability), these perceptions can cause consumers to purchase products that are objectively rated worse.

Importantly, given the ever-increasing ease with which consumers can rate items like books, employers, or travel guides, the number of product ratings that consumers typically encounter are quite high (e.g., Bank of America 2018; Goodreads 2018). When the number of reviews is high—say in the thousands—average ratings closer to the endpoints of the rating scale are statistically more likely to have smaller standard deviations than those closer to the midpoint. Thus, when the number of reviews is high, a 4.10-star average has smaller expected dispersion than a 4.0-star average.

Yet, despite this statistical property, we predict that consumers do not understand this relationship and perceive greater disagreement among the underlying ratings that comprise a non-whole-number average due to the representativeness heuristic. Computing the expected dispersion associated with a summary statistic is complex, and so consumers perform this judgment in part by automatically substituting the related task of assessing whether there is an individual rating that fits the average rating prototype. When such a match is present (e.g., an individual rating of 4 looks like the average 4.0), consumers expect more instances of that specific individual rating than otherwise, leading to perceptions of less dispersion in the distribution underlying the average.

Six experiments (total N=12,460) reveal consistent evidence of the hypothesized effect and demonstrate its consequences. Across the experiments, we employ three distinct dependent measures of perceived dispersion, demonstrating convergent validity. To aid in establishing a high level of ecological validity, we largely examine instances in which individual ratings must be whole numbers on a 5-star scale (Modus 2018) and focus on the comparison of 4.01, 4.10, and 4.11 (“non-whole-number”) and 4.0, 4.01, and 4.00 (“whole-number”) averages. Moreover, this comparison of whole-number and non-whole-number averages minimizes objective rating differences, and the predicted direction of our effect is not confounded by statistical likelihood (e.g., 2.00 vs. 2.01; expected dispersion is larger for 2.01) nor a “left-digit bias” (e.g., 1.99 vs. 2.00). Our effect is robust to the comparison of other whole-number and non-whole-number averages on non-5-star scales, and still operates when these averages are accompanied by histograms displaying the actual individual ratings that make up the average.

Each experiment employed a similar study-design. Participants viewed 10-13 items in random order. Each item had a high and unchanging number of ratings (e.g., 1,333), but was randomly assigned a target (e.g., 4.00 or 4.1) or non-target average rating (e.g., 3.63).
Non-target ratings helped conceal the nature of the experiment from participants (40%-54% of the average ratings were non-target ratings across experiments) and are not discussed further.

In experiment 1, 1,495 MTurkers encountered 10 items (e.g., campus food, mutual fund, employer on Glassdoor) with randomly assigned average ratings. For each, participants constructed their perceived distribution of the ratings making up the average via a distribution builder (Andre 2016). Across all stimuli, participants constructed distributions with lower standard deviations for whole-number average ratings than non-whole-number average ratings, $t=7.15, p<.001$. Providing initial evidence for our theorized representativeness mechanism, this effect was driven by an increase in the proportion of 4-star ratings that participants allocated to whole-number averages, $r=5.69, p<.001$.

Experiment 2 (1,519 MTurkers) replicated experiment 1 (perceived dispersion: $t=4.18, p<.001$; proportion of 4-star ratings: $t=3.43, p<.001$) using 10 new items (e.g., car brakes, doctors). More importantly, participants indicated higher choice intentions when items were paired with whole-number average ratings (i.e., averages that were objectively lower; $t=2.97, p<.01$), and this effect was mediated by the standard deviations of the constructed distributions, $z=2.59, p=.01$.

Experiments 3A-3C illustrated the dispersion effect in a real-world context (Facebook advertisements) using another measure of perceived dispersion (consensus). In each experiment, participants encountered 13 Facebook advertisements for items (e.g., umbrella, veterinarian) with randomly assigned average ratings. Perceived reviewer consensus was higher for items with whole-number average ratings in experiment 3A (1,485 MTurkers; $t=6.38, p<.001$), experiment 3B (1,955 MTurkers; $t=9.45, p<.001$), and experiment 3C (2,998 Prolific participants; $t=17.18, p<.001$). Further, perceived consensus mediated participants’ increased consideration of the items’ rating when purchasing (3A: $z=5.35, p<.001$) and increased likelihood of clicking on the advertisement (3B: $z=7.23, p<.001$; 3C: $z=11.54, p<.001$).

Experiment 4 (3,008 MTurkers) provided additional evidence for the representativeness mechanism using a different measure of perceived dispersion (agreement). Prior to encountering 10 items from a bogus website, participants were randomly assigned to learn that reviewers on this website could rate products either using whole numbers or to one decimal point. This manipulated whether reviewers were able to select an individual rating (4.1) that fit the average rating prototype for a 4.10 average rating. Consistent with a representativeness account, participants perceived greater agreement for 4.10 average ratings than other non-whole-number averages when reviewers could rate products to one decimal point and a 4.1 rating was possible to be selected, but not when reviewers could rate products using whole numbers. Further, the difference in perceived agreement among reviewers between 4.00 and 4.10 average ratings was attenuated when reviewers could rate products to one decimal point and a 4.1 rating could be selected, $t=2.63, p=.009$.

Consumers perceive more from average product ratings than merely information about product quality. This research on how consumers mentally represent summaries of individual judgments extends a numerical cognition literature that largely focuses on the interpretation of individual numbers.

**The Commission Effect**

**EXTENDED ABSTRACT**

In addition to their fixed salaries, many employees—particularly salespeople—receive additional monetary compensation based on the sales they manage or generate. In fact, U.S. firms annually spend over $200 billion on variable sales force compensation and salespeople earn approximately 40 percent of their total pay as a result of sales-based incentives (Zoltners, Sinha, and Lorimer 2006).

A common compensation structure is the commission plan, in which a commission rate is multiplied by the gross sales attained by a salesperson to determine his/her monetary payout. For any single transaction, the same payout (e.g., $1,000) may be earned by a relatively high commission rate and a low gross sales amount (e.g., 10% commission rate on a $10,000 gross sale) or by a relatively low commission rate and a high gross sales amount (e.g., 1% commission rate on a $100,000 gross sale). The present research explores whether an identical monetary payout is evaluated differently in these two situations.

Although the principle of frame invariance (e.g., Arrow 1982; Kahneman and Tversky 1986) would expect evaluations to be unchanged in each situation, there are several reasons to believe that high gross sales amounts might produce higher evaluations. Prior work has noted that money is “physically and conceptually finite and tangible” since it can be touched, counted, and held in one’s hand (MacDonnell and White 2015). Since commission rates are typically expressed as percentages and therefore less tangible, employees might be expected to rely more on their evaluation of the gross sales amount when judging their own dollar payout. This prediction is consistent with Monga, May, and Bagchi’s (2017) demonstration of elicitation procedure compatibility.

In contrast to these alternatives, we predict that employees will rely more on their commission rate than the gross sales amount when evaluating a specific dollar payout. As a result, they will evaluate the same monetary payout more [less] favorably if it stems from a high [low] commission rate and a low [high] gross sales amount. The basis for this commission effect prediction comes from general evaluability theory (Hsee and Zhang 2010), which states that individuals rely more on attributes that are easy-to-evaluate independently when making isolated judgments (Hsee 1996). We propose that commission rates are easier-to-evaluate because they are bounded on both sides (0-100%). They are consequently less variable than gross sales amounts, which may potentially differ for each transaction. Five experiments document the commission effect and provide evidence that evaluability serves as an underlying mechanism.

In experiment 1, participants imagined being a salesperson who had either received a 20% commission on a $5,000 gross sale amount (high rate condition) or a 10% commission on a $10,000 gross sale amount (low rate condition). We also varied whether rate information was presented before or after the gross sales amount to test. Participants evaluated the attractiveness, size, and value of the dollar payout that they would receive for this specific transaction. Despite the dollar payouts being equivalent in all conditions, we found a main effect of commission rate magnitude ($F(1, 369) = 11.39, p = .001, \eta^2_p = .03$), such that participant evaluations were higher in the high rate condition ($M_{high} = 6.19$ vs. $M_{low} = 5.59$); no order effects or interactions were observed.

Subsequent experiments employed the same basic paradigm, although the specific stimuli and numerical values varied by study. In experiment 2, we found that payout evaluations were higher when the commission rate was high versus low ($F(1, 401) = 5.56, p < .02, \eta^2_p = .01$), even when the computed dollar payout was modestly higher in the low rate condition ($\$41.10$ vs. $\$39.90$). Experiment 2 also showed that the commission effect persisted irrespective of participants’ numeracy and whether they had been explicitly instructed to calculate the dollar payout. Experiment 3 ruled out the concern that our prior results were due to different inferences about effort by asking participants to evaluate a potential commission plan rather...
than a completed transaction (as in the prior studies). Even though at each tier of sales performance, participants in the high commission rate and low commission rate conditions would earn identical dollar payouts, the higher commission rate plan was nevertheless preferred ($F(1, 252) = 15.05, p < .001, \eta^2 = .06$).

Experiments 4 and 5 demonstrated the role of evaluability in producing the commission effect. Experiment 4 maintained our typical high rate (24% commission rate on a $2,000 sale) and low rate (12% commission rate on a $4,000 sale) conditions but included two additional conditions in which commission rates were both low in absolute terms, albeit still high (.024% commission rate on a $20,000 sale) or low (.012% commission rate on a $40,000 sale) relative to one another. Because they were both so low, we expected these two conditions to be indistinguishable when evaluated separately. Consistent with this prediction, we observed a significant interaction ($F(1, 264) = 4.31, p = .039, \eta^2 = .02$), such that the commission effect was replicated when comparing the first two conditions ($F(1, 264) = 10.80, p = .001, \eta^2 = .04$) but eliminated when comparing the low absolute commission conditions ($F(1, 264) = 22, p = .64, \eta^2 = .01$). Experiment 5 provided additional support for the proposed evaluability mechanism by showing that participants were more likely to use the less-evaluable gross sale amount when a reference point (i.e., the average gross sale amount) was included. We obtained a significant interaction effect ($F(1, 557) = 7.21, p < .01, \eta^2 = .01$), such that the commission effect was observed with no reference ($F(1, 557) = 11.98, p = .001, \eta^2 = .02$) but eliminated when the reference was included ($F(1, 264) = .17, p = .69, \eta^2 = .01$).

Taken together, these experiments provide robust evidence of the commission effect and implicate evaluability as an underlying mechanism. In addition to contributing to our understanding of numerical cognition, framing effects, and evaluability, this research provides actionable managerial implications for firms and managers that use commission plans to motivate and reward their employees.

**Left-Right or Top-Down? The Effect of Horizontal versus Vertical Scale Orientation on Consumer Judgments**

**EXTENDED ABSTRACT**

Managers and researchers widely use surveys to understand human behavior and preferences. Online platforms offer the option of orienting scales horizontally versus vertically as a design choice, or sometimes automatically default to a horizontal orientation for computer interfaces and vertical one for mobile interfaces. This automatic change in orientation is based on the assumption that orientation does not affect responses.

However, based on previous work demonstrating powerful implicit and associative effects (Dehaene 2001, 2003), which includes the tendency to anchor on the left-hand starting point and adjust to the right when using scales (Chan 1991) and work demonstrating that the human visual field is wider than it is tall (Deng et al. 2016; Kunnapais 1957; Morikawa and McBeath 1992), we predict that scales with vertical orientation will result in lower evaluations than those with horizontal orientation. More specifically we predict this is because people pay less attention to the endpoint of a scale when vertically versus horizontally oriented, and therefore adjust towards the endpoint less.

In experiment 1 (undergraduate students, $n = 159$) participants answered the five Deiner et al. (1985) Life Satisfaction Scale questions on either a horizontally or vertically oriented scale ($1 = strongly disagree, 7 = strongly agree$). A mixed ANOVA with orientation as a between subjects factor and life satisfaction question as a between subjects factor revealed a main effect of orientation ($F(1, 157) = 5.32, p = .02$) and question replicate ($F(4, 628) = 25.29, p < .001$). The interaction between the two was not significant. Participants reporting being happier when using a horizontally ($M_H = 5.13$) versus vertically ($M_V = 4.70$) oriented scale.

Because experiment 1 utilized the Qualtrics spacing defaults (e.g. horizontal wide, vertical narrow), experiment 2 varied the spacing of the scales as wide versus narrow to test whether this is an implicit and associative effect versus one that is due to physical placement. mTurk participants ($n = 601$) completed the Lyubomirsky and Lepper (1999) Subjective Happiness Scale either horizontally or vertically oriented, with either wide or narrow spacing. A mixed ANOVA with orientation and spacing as between subjects factor and happiness questions as between subjects factor revealed only a main effect of orientation ($F(1, 1191) = 4.21, p = .04$) and replicate ($F(2, 1194) = 55.58, p < .001$ and no other significant effects, suggesting that spacing cannot account for the effect.

Experiment 3 (mTurk panel, $n = 125$) tests for evidence of the Verticality Effect in a non-affective domain. Participants were shown before and after treatment photos by a silicone scar sheet with product information, then asked to judge how much better the scar looks after treatment on a 9-point scale ($1 = not at all better, 9 = much better$) with either horizontal or vertical orientation. Those using a scale with horizontal orientation ($M_H = 6.30$) judged the improvement as larger than those using a scale with vertical orientation ($M_V = 5.61, F(1, 123) = 5.73, p = .02$), even when shown identical photographs.

Our theorizing suggests that the effect of orientation stems from inattention to and adjustment towards the endpoint of the scale when vertically oriented. If this is the case, the Verticality Effect should be attenuated for judgments where the endpoint is less relevant (experiment 4) or where attention is drawn to the endpoint (experiment 5). Participants in experiment 4 (mTurk panel, $n = 221$) were asked to indicate their purchase intention for 15 products in 3 products categories on a 7-point scale ("How likely are you to buy this product?", $1 = unlikely to buy, 7 = likely to buy) with either horizontal or vertical orientation. For each product, they were shown a product name, photograph, moto, and quality rating designated by an independent rating agency. For each product category, participants were shown a product with a quality rating of 1, 2, 3, 4, and 5 in order to ensure a distribution of responses across the range of the rating scale to test that the effect of orientation increases as the scale values increase to the right. As expected, participants’ purchase intention increased for higher quality products ($F(1, 3092) = 1912.30, p < .001$). The interaction between quality level and orientation was significant ($F(1, 3092) = 8.55, p = .003$). Furthermore, contrasts at each quality level revealed that the effect of orientation increases as quality level increases and is strongest for quality levels 4 and 5 (ps < .0001).

If the effect of orientation stems from relative inattention to the scale endpoint when using vertical versus horizontal scales, then drawing more attention to the endpoint during judgments should attenuate the Verticality Effect. Because prior research has shown that people tend to first read and anchor on the left side of a scale (Chan 1991) and process numerical information on scales before verbal information (Tourangeau et al. 2007), reversing the numerical scale from 9-to-1 should attenuate the verticality effect by making the endpoint of the scale more salient by making it the visual starting point. Experiment 5 utilized the same stimuli as experiment 3, but added the additional factor of numerical direction of the scale that is either increasing (1-to-9) or decreasing (9-to-1). We predict that the effect of orientation will be attenuated for decreasing numerical direction. The results of the experiment revealed a significant effect of orientation ($F(1, 294) = 9.40, p = .002$) and an interaction between orientation and numerical direction ($F(1, 294) = 3.72, p = .05$). The effect of
orientation was significant with increasing numerical direction ($M_{p} = 6.72$ versus $M_{r} = 5.85$; 1-to-9, $F(1, 294) = 12.13, p = .0001$), but not decreasing numerical direction ($M_{p} = 6.21$ versus $M_{r} = 6.01$; 9-to-1, $F(1, 294) = .42, p = .42$). The results of this research demonstrate a robust and highly managerially relevant effect of orientation on consumer judgments while offering new insights in theory development for how visual perception and implicit associations can affect judgments.

Paper #4: Word of Mouth: A Review and Directions for Future Work
Jonah Berger, Wharton School of the University of Pennsylvania, USA

SESSION OVERVIEW
Consumers are exposed to word of mouth (WOM) all the time. Yet, despite the prevalence of WOM in consumers’ daily lives, and the clear importance of understanding the factors that both induce WOM and influence how it is perceived, the topic remains relatively understudied. What sender and recipient variables stimulate WOM and how do these variables affect WOM content? How can WOM content influence how it is perceived? Three talks provide cutting edge insights to answer these and other questions. A fourth review talk synthesizes recent work in the space and outlines fruitful directions for future research.

The session opens with a paper by Du Plessis, Schaerer, and Dubois, which identifies a characteristic of WOM senders and recipients (hierarchical rank) that affects the content of the messages that consumers share. They find that consumers share less positive messages with recipients below them in the hierarchy because they have less desire to connect with these lower ranked recipients.

Bechler, Tormala, and Rucker follow up with a related paper which identifies a recipient characteristic (attitude position) that stimulates WOM, finding that consumers prefer to direct persuasion efforts toward individuals whose attitudes could change qualitatively (e.g., from negative to positive) rather than non-qualitatively (e.g., from positive to more positive) because this type of attitude change is perceived as greater and is inferred to have more impact on the recipients’ subsequent behavior.

The session then shifts toward a discussion of the WOM content itself. Morgan, Chen, and Dommer investigate how the disclosure of intimate personal information influences the perceived value of WOM, discovering that WOM value is reduced when reviewers share intimate personal details because revealing these details is perceived to be socially inappropriate. Those who share intimate personal information when reviewing a product are less liked and their reviews are less persuasive, decreasing product purchase likelihood.

Last, keeping with the conference theme of “Becoming Wise” and highlighting “the aggregate wisdom” in the WOM domain, Berger concludes the session with a review of research in this area. He will synthesize past WOM research with the novel insights from the papers presented earlier in the session, provide a framework to organize these existing findings, and discuss directions for future WOM research.

Collectively, these talks further our understanding about a growing area of consumer research: WOM. Theoretically, this session is important because it represents an early step towards understanding something that is extremely prevalent in consumers’ lives, but researchers still know little about. Practically, this session is important because it provides psychological insight into a wide array of WOM behaviors, such as WOM within social hierarchies, WOM with persuasion intentions, and WOM in product review contexts. The questions posed and answered in the session will expand and synthesize our understanding of the factors that induce WOM and influence how it is perceived, and hopefully spark new research on this important topic.

Sharing Like a Boss: How a Consumer’s Position in the Hierarchy Influences Word-of-Mouth Valence

EXTENDED ABSTRACT
Understanding WOM is crucial because brand success often depends on the type of information people share. Particularly important to marketers is understanding what causes consumers to share positive or negative information, as WOM valence plays a crucial role in the success or failure of products and services (Chevalier & Mayzlin, 2006). One important factor that shapes WOM valence is with whom consumer are communicating (Berger, 2014). Empirical research has established two important audience characteristics that affect WOM valence: tie strength and audience size. Past research shows that people share more positive information when communicating with strangers than with friends (Dubois, Bonezzi, & De Angelis, 2016; Chen, 2017) as well as with larger (vs. smaller) audiences (Barasch & Berger, 2014).

Although tie strength and audience size are important, we propose a third dimension that can explain when consumers share more positive or negative information: the hierarchical relationship between WOM senders and recipients. Social hierarchies, defined as “an implicit or explicit rank order of individuals or groups with respect to a valued social dimension” (Magee & Galinsky 2008, p. 354), permeate almost every aspect of society, and, as a result, people often share WOM with individuals that occupy higher or lower relative rank. Indeed, in a survey of 255 working adults, we found that 90.2% regularly engage in WOM at work—an inherently hierarchical environment.

Given the prevalence of WOM in hierarchies, we investigate whether, when and why the hierarchical relationship between a WOM sender and recipient influences WOM valence. We propose that consumers share less positive messages with lower (vs. equal or higher) rank recipients. Because higher-ranked people have an increased ability to control their own and others’ outcomes, they are less dependent on others (Fiske, 1993). Consequently, higher-ranked people have lower desire to affiliate with those below them in the hierarchy (Lammers, Galinsky, Gordijn, & Otten, 2012) and may...
even actively engage in distancing behaviors (Earle, Giuliano, and Archer 1983). Since sharing positive information facilitates interpersonal closeness (Brisette, Scheier, & Carver, 2002), and people share positive information to foster social connections (Bell, 1978), we predict that senders will share less positive WOM with recipients who are lower (vs. equal or higher) in rank.

In Study 1 (n=393), participants watched an animated short film and either wrote down their thoughts about the film (baseline condition), or what they would say about it to their peer (equal-rank condition), supervisor (low-rank condition), or subordinate (high-rank condition). We created a positivity index by subtracting the number of negative attributes from the number of positive attributes. Participants in the high-rank condition sent less positive messages (M=82, SD=2.15) than participants with low rank (M=1.54, SD=2.14), F(1,391)=4.55, p<.05, baseline participants (M=1.58, SD=2.82, F(1,391)=5.19, p<.05), and participants in the peer condition (M=1.68, SD=2.27, F(1,391)=6.32, p=.01).

Study 2 tested the consequences for message reception. In Part 1, participants (n=35) read a description of car and wrote a message about it to a colleague ranked lower (vs. higher) to them in their team. In Part 2, participants (n=358) read one of the messages from Part 1 and indicated how much they would pay, how willing they are to buy, their intention to inspect and their attitudes towards (α=.96) the car. They also indicated their intention to contact the seller. Multilevel mediation analyses with sender rank as independent variable (1=higher-rank sender, -1=lower-rank sender), and WOM valence as mediator, revealed a significant and negative indirect effect of sender rank on recipients’ willingness-to-pay (ab=.32, SE=.17, 95% LLCI=.75, ULCI=.08), willingness-to-buy (ab=4.40, SE=.19, 95% LLCI=.81, ULCI=.11), intention to inspect (ab=3.58, SE=.19, 95% LLCI=.77, ULCI=.08), intention to contact seller (ab=.35, SE=.17, 95% LLCI=.73, ULCI=.08) and product attributes (ab=.39, SE=.17, 95% LLCI=.75, ULCI=.12), through WOM valence.

Study 3 tested our proposed mechanism in a competing mediation model. Participants (n=203) were randomly assigned to a high or low rank condition. We also measured need for affiliation (α=.85), felt responsibility toward interaction partner (α=.91), and role expectations (α=.44, p=.001). Replicating previous studies, participants in the high-rank condition (M=.55, SD=2.26) wrote more positive messages than participants in the low-rank condition (M = 1.19, SD=2.03), t(201)=2.15, p<.05. Importantly, the competing mediation revealed a significant indirect effect through need for affiliation (ab=−.11, SE=0.05, 95% LLCI=−.24, 95% ULCI=−.03), but not through responsibility (ab=0.03, SE=0.02, 95% LLCI=−.02, 95% ULCI=0.06), or role expectations (ab=0.03, SE=0.03, 95% LLCI=−.05, 95% ULCI=0.06).

In Studies 4-5 we provide additional process evidence by manipulating need for affiliation. In Study 4, participants (n=472) watched a short film and wrote down what they would say about it to their supervisor (low-rank condition) or subordinate (high-rank condition). A third condition was included in which participants were instructed to write a message to their subordinate but were told that the goal of writing their message was to bond with the recipient (high-rank + affiliation motive condition). Participants in the high-rank condition wrote less positive messages (M=93, SD=1.99) than participants in the low-rank condition (M=1.47, SD=1.90), F(2,469)=6.72, p<.01, but not when their affiliation motive was activated (M=1.65, SD=1.66), F(2,469)=.80, p=.37. There was no difference in message positivity between the low-rank and the high-rank + affiliation conditions, F(1,310)=.86, p=.35.

In Study 5, we varied need for affiliation by manipulating whether senders expect to interact with the recipient in the future. In interactions where people expect to depend upon one another in the future (vs. not), the need to affiliate increases (Danheiser & Graziano, 1982). Participants (n=394) again watched an animated short and were then randomly assigned to a 2(rank: lower, higher) x 2(expect future interaction: no, yes) between-subjects design. Supporting our hypothesis, when senders did not expect to interact with the message recipient in the future, those with higher rank sent less positive messages (M=41, SD=1.91) than those with lower rank (M=1.12, SD=2.13, F(1,393)=5.54, p<.05). When senders expected to interact with the message recipient in the future, there was no difference in WOM valence, F(1,393)=.04, p=.84.

Jointly, these studies contribute by identifying a novel sender characteristic that influences WOM content (hierarchical rank) and suggest that the need for affiliation is a key driver of positive WOM.

**Choosing Targets: How Expectations of Qualitative Change Influence Word of Mouth**

**EXTENDED ABSTRACT**

Imagine a word of mouth (WOM) campaign designed to enhance consumers’ attitudes toward some brand, product, policy, or political candidate. Would it be better to target people like Consumer A, who would shift her attitude from very negative to just slightly negative, Consumer B, who would shift her attitude from slightly negative to slightly positive, or Consumer C, who would shift her attitude from slightly positive to very positive? WOM is an increasingly important topic in consumer research, and in the attitudes and persuasion domain more specifically. In attitudes and persuasion research, multiple recent investigators have turned their attention from identifying the factors that drive attitude change to those that stimulate WOM, advocacy, and the motive to persuade others. However, one question this growing body of work has yet to address: How do people select the targets of their messages? To whom do people prefer to send WOM or other persuasive appeals?

This research examines how the type, or nature, of attitude change senders expect to observe drives their target selection. One possibility, the null hypothesis, is that WOM senders are essentially indifferent about the type of attitude change their messages induce. For example, if they believe they can cause 2 points of attitude change on a 9-point scale, they may care little about where on the scale that change occurs. If true, we might expect WOM senders to show no preference among Consumers A, B, and C as potential persuasion targets. Alternatively, an attitude strength hypothesis (Petty and Krosnick 1995) might predict that senders would prefer to target consumers like A or C, because those consumers would shift in attitude extremity. Attitude extremity is a central dimension of attitude strength and changes in attitude strength can cause changes in behavior. Therefore, Consumers A and C might be perceived as experiencing, and indeed might actually experience, the most meaningful behavior change if targeted.

Although these hypotheses have merit, we propose the qualitative change hypothesis and posit that WOM senders prefer to target people like Consumer B, because those consumers’ attitudes shift across a neutral threshold from one valence to another. People perceive qualitative attitude change (i.e., changes in valence; e.g., from negative to positive) as greater than otherwise equivalent non-qualitative change (i.e., changes within valence; e.g., from positive to more positive), and as a result infer that targets changing qualitatively will exhibit greater behavior change (Bechler, Tormala, and Rucker 2019). The current research investigates whether this shapes the manner in which people select persuasion targets.
TMI: How and Why Personal Self-Disclosure Affects the Persuasiveness of Consumer Word-of-Mouth

EXTENDED ABSTRACT

In online reviews, reviewers often self-disclose personal information along with their product experiences. Conventionally, the wisdom suggests adding a personal touch via disclosure might make a review more helpful. Research in interpersonal relationship shows that sharing personal information brings people closer together and induces liking (Collins and Miller 1994). Persuasion research shows that liking of the speaker induces greater persuasion (Roskos-Ewoldsen and Fazio 1992). However, does this apply to online reviews? Does reviewers’ sharing of personal information increase review usefulness?

We posit that one important way the online review context differs from previous work (that shows a positive effect of personal disclosure) is that review platforms are typically filled with strangers. In contrast to interactions with friends – where personal disclosure is desired and appropriate (Collins and Miller 1994) – interactions with strangers tend to stay at the surface, where the sharing of intimate personal information is often seen as socially inappropriate (Aron et al. 1997; Chaikin and Derlega 1974). As a result of this norm violation, readers are likely to dislike reviewers who disclose personal information and find their reviews to be less persuasive (i.e., usefulness). These ideas are tested and confirmed across four studies.

Study 1 examines the effect of reviewer intimate personal disclosure (PD) on review persuasiveness, examining nearly 1,000 reviews for electronic devices (e.g., Kindle) from Amazon.com. To capture PD, we use Linguistic Inquiry and Word Count (LIWC; Pennebaker et al. 2015), creating a measure for usage of words related to the ‘Personal Concerns’ category (e.g., work or money) within the review text (higher values indicate higher usage and more PD). According to LIWC, ‘Personal Concerns’ encapsulates reviewer-focused information, providing a suitable means to measure PD. To capture review persuasiveness, we counted the number of “yes” votes a review receives when readers are asked “was this review helpful to you.” Given the count variable DV, a Poisson regression (with log-link function) analysis revealed a significant negative relationship between the number of helpful votes and PD ($\beta = -0.05$, $p < .001$). Using a real-world dataset, study 1 demonstrates that PD adversely affects persuasiveness.

Study 2 replicates study 1 in a lab setting. We showed participants the same restautant review, and manipulated whether the review contained or did not contain PD in the beginning. Importantly, we address a potential alternative explanation. Since consumers are limited in their processing resources (Petty and Cacioppo 1984), PD placed at the beginning of the review may preclude readers from seeing key product-relevant information that appear later. To address this possibility, we also added a condition where PD appeared at the end of the review. If it is social impropriety, as we argue, PD position should not matter; however, if results are due to preclusion of relevant information, then the effect should be attenuated when PD appears at the review’s end. As such, participants were randomly assigned to one of three conditions (review type: no PD vs. PD-beginning vs. PD-end) where review usefulness served as the DV. Both reviews with PD ($M_{PD} = 5.39$) were less useful than the no PD review ($M_{noPD} = 6.02$, $p < .001$). Critically, no difference emerged between the PD reviews ($M_{PD-beginning} = 5.42$ vs. $M_{PD-end} = 5.36$, $p = .77$).

Study 3 illuminates the underlying process while also addressing additional potential alternative explanations. Our theory predicts a serial process whereby consumers 1) view reviewers’ PD as socially inappropriate, 2) thus lowering reviewer likeability, thereby...
3) reducing interest for the reviewed product. However, one could argue that PD operates in two alternative ways – by reducing the perceived relevance of the review or by reducing perceived similarity to reviewer (e.g., readers think they are dissimilar to those who disclose personal information). Study 3 tests our underlying mechanism via mediation along with these alternative processes. Participants read a review for a blender with (vs. without) PD (e.g., embarrassment with weight), while holding constant all other information. Participants rated their purchase likelihood and attitude towards the blender (composite DV; \( r = .87, p = .01 \)). Participants assessed review appropriateness across three items (a(3)=.94): 1) socially proper, 2) appropriate amount (of PD), and 3) appropriate inclusion (of PD, 1=not all appropriate, 7=very appropriate). To address alternative explanations, participants also rated relevance of the review as well as perceived similarity to the reviewer. Results revealed that participants had marginally higher attitude and purchase intention when shown the review without PD than the review with PD (\( M_{no PD} = 4.74 \) vs. \( M_{PD} = 4.30; p = .079 \)). Using PROCESS model 81 (Hayes 2018), we tested and found a significant serial mediation model (\( \beta = -.26, 5000 BS 95\% CI[-.4546, -.1049] \)) showing that the PD (vs. no-PD) review was seen as inappropriate, thereby reducing reviewer likeability, and lowering attitude and purchase likelihood for the reviewed product. These results held after controlling for the effect of relevance and similarity.

If PD negatively affects review persuasiveness because of norms violation, then for product categories where sharing personal information is expected and socially appropriate (e.g., high-intimacy products such as personal medications [preparation-H]), the negative effect of PD might be attenuated. We investigate this in study 4 using a secondary dataset from Amazon.com (N = 1,997 reviews). We expected to replicate our effect in low-intimacy products (e.g., statistics textbooks) but that this should be attenuated in high-intimacy products (e.g., self-help books). We used the same IV (LIWC’s ‘Personal Concerns’ words) and DV from study 1. A Poisson regression (log-link function) revealed a significant interaction between product category (low vs. high intimacy) and the use of personal concern words (\( \beta = .028, p < .001 \)). As predicted, the negative effect of PD is present for low-intimacy products (\( \beta = -.03, p < .001 \)) but attenuated for high-intimacy products (\( \beta = -.002, p = .583 \)), suggesting that norms for high-intimacy products attenuate PD’s negative effect on review persuasiveness.

This work extends WOM research, showing that PD can irrationally reduce review persuasiveness, and identifying reviewer self-disclosure as an important factor in WOM. These findings further contribute to a budding research stream examining the joint effect of linguistic content and judgement of reviewers on WOM persuasiveness.

Word of Mouth: A Review and Directions for Future Work

EXTENDED ABSTRACT

Word of mouth is frequent. People share stories with friends, information with colleagues, and recommendations with neighbors. They talk about whether a restaurant was good, a movie was engaging, and a new product lived up to the hype. The emergence of social media and online reviews has only increased the frequency and breath of consumer conversations.

Would of mouth is also important. The attitudes, preferences, recommendations, and mentions of others have an important impact on consumer behavior. Positive reviews increase book sales. Colleague recommendations increase adoption of pharmaceutical drugs.

And by some estimates, word of mouth has more than twice the impact of traditional advertising.

But while the importance of word of mouth is clear, less is known about why people talk about and share some things rather than others. Why do certain products get more word-of-mouth? Why do certain rumors spread faster than others? And why does certain online content go viral? How does the audience people are communicating with, as well as the channel they are communicating through, impact what gets shared? How does the dynamics of back and forth word of mouth truly evolve? Why do some conversations last longer and what drives topic switching?

To help build wisdom in this area, this talk will address these, and related questions, as it integrates various research perspectives to shed light on the behavioral drivers of word-of-mouth. It provides an integrative framework to organize research on the causes and consequences of word-of-mouth and outlines additional questions that deserve further study.

First, the talk will review prior work in the space, and talk about how it has evolved over time. Berger (2014) argued that interpersonal communication is goal driven and serves five key functions. These include:

1. Self-Presentation,
2. Emotion Regulation
3. Information Acquisition
4. Social Bonding
5. Persuading Others

Further, building on prior work the paper argued that who talks, to whom, about what, through which channel, with what effect, was a useful framework to organize existing work and drive further work in the space.

In the years since this paper was published through, there have been dozens of new findings and results. The talk will start with the prior framework, integrating new findings and pointing out places where they support, or refute, prior hypotheses. Further, this second generation of word of mouth research has begun to more deeply examine moderators, shedding light on how various motives combine to shape what people share, and how who people are talking to, and the context in which they are sharing, shapes transmission.

Second, the talk will outline some areas that seem particularly fruitful for further research. One interesting direction is conversational dynamics. Almost all existing research on word of mouth involves a single transmission occasion. Whether some news articles get shared more than other of whether someone talks about a specific product or service in a single outbound message to another person. But while such simplistic analyses have provided a variety of important findings, they lack the depth of most real world interpersonal communication. When someone texts, calls, or talks to someone else, they don’t just share one thing. They share a variety of things as part of a larger back and forth conversation.

How do such dyadic, dynamic conversation shape word of mouth? What topics do people tend to start with and how do conversations evolve from one topic to the next? What leads some topics to last longer than others and how do characteristics of the communicators, and their similarity, shape topic length? What drives topic death and conversational closure? These are only a small handful of the interesting questions available for consumer behavior researchers to study. I’ll mention some of my own preliminary data in this space (how similarity shapes topic evolution and concreteness shapes topic death) as well as some emerging work from a variety of other labs.

Another interesting direction is the importance of language. While a good deal of work has examined what people talk about, there has been less attention to how they talk about it. But an emerg-
ing stream of work has begun to highlight how subtle differences in language can both signal things about the sharer (and their attitudes) and shape consumer behavior.

Finally, I’ll briefly mention the emergence of automated textual analysis. Rather than having to ask people whether they would share something in the lab, researchers can now better examine real social transmission in the field. These tools open up a range of exciting areas for further study.

In sum, what we know about word of mouth is clearly dwarfed by what we don’t. That said, this talk will attempt to review what we do know, provide a framework to organize existing research, and outline potential directions for future work in the area.

SESSION OVERVIEW

Americans hold over $800 billion in credit card debt. The average cardholder owns four credit cards, often with high interest rates that can cause debt to spiral out of control. Some people even hold high-interest credit card debt and savings simultaneously, a tendency called “the credit card debt puzzle,” which can be extremely harmful. Understanding how consumers use credit cards and the processes that lead consumers to accumulate excessive debt is of paramount importance. The difference between wise and foolish decision making in this high-stakes domain can be the difference between financial security and financial turmoil.

How do consumers pick among the many credit cards available to them? How do people determine which debts to pay off first? What factors make people more likely to pay off debt? The papers in this session will help answer these questions. In so doing, they will advance the field’s understanding of consumer financial decision making, as well as our understanding of the heuristics, biases, and strategies people use more generally. Though the talks focus on consumer financial decision making and credit card decisions in particular, there is also a diversity of topics that will make this symposium interesting to a broad audience.

In the first paper, Olivola, Pretnar, and Montgomery use data from a large North American bank with over 3 million observations to examine factors that help or harm consumers’ ability to make debt repayments. They show that some factors, including whether consumers buy a durable rather than non-durable good, impact debt balances long-term.

In the second paper, Hirshman and Sussman demonstrate that minimum payments can interfere with people’s ability to make wise debt repayment decisions. Minimum payments make people less likely to choose the optimal strategy of paying off debt from higher-interest credit cards first, even though most people are aware that paying off high-interest debt first is the best strategy.

In the third paper, Mrkva, Webb, and Johnson focus on how people choose a credit card. They find that impatient, present-biased individuals are less willing to search for the optimal credit card, which causes them to choose cards that accumulate higher fees. Finally, Hsee, Li, Zeng, and Imas examine how people allocate money when there are multiple accounts, some with more resources than others. They find that people allocate too much toward smaller accounts.

The potential audience for this session is broad. Though the talks focus on consumer financial decision making and credit cards, it will be interesting to many. For example, three of the papers cover a novel heuristic or bias in decision making, several are rooted in behavioral economics, several use big data, some focus partly on time preferences and intertemporal choice, two have clear policy implications, one examines consumer search and information processing, and one has direct relevance for researchers who study perspective-taking and economic games.

All talks are based on papers in the late stages of development. All four papers are either currently being prepared or will soon be prepared for submission to A journals.

A Structural Test of Mental Accounting and Consumer Fungibility from Credit Card Expenditures

EXTENDED ABSTRACT

The theory of mental accounting suggests that consumers treat different sources of money and different expenditures differently (Thaler 1999). One implication of mental accounting is that consumers may be more likely to spend with credit cards than with cash or debit (e.g., Prelec and Simester 2001), particularly for durable goods purchases (Prelec and Loewenstein 1998). Under this theory, increasing the credit limit on a consumer’s credit card should increase his/her consumption, regardless of whether his/her income or wealth also increased.

We test this prediction using a unique dataset of linked credit and debit card users. Our analysis adds to the literature on mental accounting theoretically, by deriving a measure of fungibility with regards to credit and debit card usage directly from a consumer’s structural consumption/savings problem. It also adds to previous theorizing empirically by using linked household credit/debit card field data from a large North American bank to show that consumers behavior in ways consistent with mental accounting.

We construct a theoretical, economic utility maximization model that allows different consumers to exhibit different degrees of fungibility. Specifically, we incorporate the mental accounting concept of partitioned ex-ante and ex-post budgeting by splitting the household budget constraint into separate constraints for each liquidity category and then allowing consumers to choose shares of consumption for different commodities out of different liquidity sources. Specifically, we focus on credit card verses debit card expenditure, though the model is general enough to admit many more liquidity sources by simply adding a new constraint. Among other things, the model reconciles a heretofore unsolved problem in mainstream economics known as “the credit card debt puzzle,” wherein consumers simultaneously save and carry interest-bearing credit card debt (see Telyukova 2013; Telyukova and Wright 2008). Depending on individual consumers’ innate aversion to holding debt, an individual may or may not simultaneously save and carry interest-bearing debt. This preference-based explanation allows us both to solve the puzzle and reconcile the vast degree of heterogeneity observed in the data with regards to savings and debt-accumulating behavior.
Using the equilibrium fungibility condition, we empirically test whether the median consumer unit (i.e., household) in our sample exhibits perfect fungibility with respect to credit and debit card expenditure. We find that the median consumer behaves as if receiving $1 in additional credit is equivalent to receiving $2.03 in additional cash in terms of marginal consumption value. A statistical test shows that the median consumer is thus significantly non-fungible with regards credit verses debit card expenditure. However, the distribution of this trait varies substantially across consumers: 59% of our sample behave as if the consumption value of credit is higher than that of cash, whereas the other 41% behave in the opposite manner.

Our structural model of fungibility can be used to better understand how consumers across the joint income, wealth, and debt distribution respond to exogenous credit and income shocks. For example, in counterfactual simulations, we can quantify how consumers who exhibit a pronounced aversion to accumulating credit card debt respond to unexpected, adverse income shocks. Being more sensitive to debt accumulation, the model predicts that such consumers will adjust their overall consumption downward to avoid accumulating too much debt. On the other hand, a consumer unit that is not debt averse may excessively smooth their consumption in response to a negative income shock by taking on more debt to ensure that their level of consumption, and thus standard of living, remains fairly consistent over multiple periods.

Additionally, we affirm the theory of Prelec and Loewenstein (1998), that consumers are more apt to use credit cards for durable goods purchases than non-durable goods purchases, because the pain of continually paying down accrued interest on debt is offset by the stream of utility they continue to enjoy from using durable goods. Specifically, we find that the median consumer unit in our sample (of over 10,000 households) responds to a $1 increase in credit by spending $0.32 more on durable goods than if s/he received the same $1 increase in available cash. For non-durables, by comparison, this effect is less pronounced in magnitude (only $0.05 more), though still significantly greater than zero. Our empirical results are consistent with a similar analysis on U.K. credit card users (Qui-spe-Torreblanca et al. 2019). Altogether, our results both bolster previous theorizing on mental accounting and build on this theory. Our results provide a clearer picture of how people mentally represent increases in credit, cash, and debit, and how people mentally represent their expenditures across different categories. Our data also afford a powerful tests of mental accounting using a large and unique dataset of credit and debit card usage from a large North American bank.

**Minimum Payments Alter Debt Repayment Strategies Across Multiple Credit Cards**

**EXTENDED ABSTRACT**

Americans hold an increasing amount of revolving credit card debt, currently estimated at $808 billion (Federal Reserve Bank of New York 2017), on an average of four cards per cardholder (CFPB 2015). A growing body of literature suggests people do not repay their debt in the cheapest possible way (e.g., Ponce et al. 2017). Prior work explains suboptimal repayment through lack of interest rate knowledge (Seira et al.2017) or through a variety of heuristic strategies inconsistent with the optimal repayment (Gathergood et al. 2017). In particular, a laboratory examination of borrowers with multiple cards shows that they prioritize paying off smaller debts rather than high interest rate debts (Amar et al., 2011). By contrast, data from the field suggests that credit card holders use a balance matching heuristic, paying more to their largest debts (Gathergood et al. 2017).

We draw on lab and field data to provide evidence that people are knowledgeable that they should repay their highest interest rate debts first. Furthermore, borrowers do prioritize these debts to some degree. In addition, we document a dispersion effect of minimum payments. That is, minimum payments reduce participants likelihood of repaying optimally by leading them to spread their discretionary repayments (i.e., payments above the minimum) across more accounts than those without minimum payments. We find that this strategy change persists after accounting for the tendency to target minimum payment amounts (Stewart 2009), and we do not find evidence supporting widespread use of heuristics based on balance amount.

Data from the lab and field suggest consumers are sensitive to the importance of interest rates in debt repayment. Our field data comes from a budgeting app and has 39,626 months of repayment data for 1,956 unique consumers. We find that consumers repay about $132 more (t(37,789)=3.14, p=.0017, equivalent to 4% of the average balance) to their highest interest rate debt in a month, controlling for the size of their balance. These data are consistent with self-reported strategies from Mturk experiments. Many participants (47%) report repaying high interest debt is the most important element in their decision, significantly more than the second highest strategy, splitting evenly across cards (14.5%, χ²(1)=43.68, p<.001). However, of the group focused on high interest, 38.5% report wanting to pay most, rather than all, of their repayments toward their highest interest rate debt, thus insufficiently weighting interest.

We next examine minimum payments as one structural factor that may alter repayment strategies away from paying the highest interest rate cards first, further interfering with the ability to repay optimally. In study two, participants responded to a three round debt repayment scenario. Each participant had 6 credit cards to repay, with outstanding balances and interest rates stated for all cards. Participants (N=375) were randomly assigned either to have a minimum payment associated with each debt or not. In the minimum payment condition, participants faced a $25 fee per account paid below the minimum. Participants made allocations to all debts in the same table. We find that participants in the minimum payment condition were less likely to repay optimally (t(373)=2.91, p<.01). This suboptimal allocation in the minimum payment condition was driven by overdispersion. Participants made payments towards more cards, over and above the minimum payments themselves (t(373)=3.624, p<.01). We did not find evidence of substantial portions of participants paying off the smallest debt first, contrary to prior literature. We also replicated these effects in a setting where participants made one allocation per screen.

In study three, we replicated these findings utilizing a within subject design over 3 weeks. Participants (n=189) completed the self-report measures discussed previously and were then randomly assigned to one of two orders of our minimum payment and no minimum control conditions. Within-subjects, we find a marginally significant decrease in optimal play in the minimum payment version of our task (t(188)=1.698, p=.091) and a significant increase in the proportion of accounts paid above the minimum (t(188)=4.513, p<.00001). The within-subject version suggests that knowledge and individual differences are unlikely the key driver of the strategic effects.

In study four, we allow participants (N=366) to save money in addition to repaying debt. Participants in the minimum payment condition are significantly more likely to save than those without minimums (t(364)=3.20, p<.01), leading to higher interest costs incurred. In addition to repaying less, they continued to repay less optimally than those without minimums (t(364)=3.46, p<.01). Among partici-
pents who made any excess repayment, participants in the minimum payment condition allocated to more accounts above the minimum (t(360)=1.97, p<.05). These results suggest that impacts of minimum payments on strategy remain important even after allowing for the effects of targeting. Finally, in experiment five we introduce a default minimum payment condition in which minimum payments are auto-filled for the participants (i.e., the default is to pay the minimum amount on all cards; N=258). Since the optimal strategy in the default and the minimum payment conditions are the same, differences between these conditions are unlikely to be driven by decision complexity. We find that the default condition attenuates the strategic differences between the minimum payment and no minimum payment condition. Like the no minimum condition (t(167)=3.52, p<.01), participants in the default condition are more likely to use the optimal strategy (t(171)=2.16, p<.05). As a result, it is unlikely that the complexity of the optimal rule is responsible for the changes induced by minimum payments. Additionally, the increase in optimal repayment above the minimum payment condition provides evidence that actively selecting an allocation amount for each debt contributes to the strategic differences we observe induced by the minimum payments.

We provide new evidence on the strategies that lead people to repay their debts sub-optimally. Contrary to prior literature, we find people are aware of the importance of prioritizing payments to higher interest rate debts. They are sensitive to interest rates, but insufficiently so. We document a novel cost of minimum payments: minimums induce participants to spread money more evenly across accounts. Our results suggest that mandating salient presentations of interest rates could reduce the costs of borrowing for consumers.

### Searching, Fast and Slow: How Time Preferences Influence Credit Card Search and Choice

**EXTENDED ABSTRACT**

When we think about present bias, we usually think about the choices that people make. We expect people who are present biased to eat the one marshmallow now, take the smaller immediate payment, and choose the credit card with a teaser rate (Chabris et al. 2009; Reimers et al. 2009; Shoda et al. 1990).

Across four studies and four field surveys (total N = 18,405), we show that present-biased individuals are not any more likely to choose credit cards with teaser rates nor do they focus attention on or give more weight to up-front costs. Instead, they simply search less for all pieces of information about credit cards, with low introductory rates. This suggests that present bias affects the process through which individuals make credit card decisions, with low introductory rates. This suggests that present bias affects the process through which individuals make credit card decisions, not the weights they place on different attributes.

As predicted, present-biased individuals searched substantially less, opening fewer attribute boxes (t = 7.06, p < .001). This effect held when we added covariates to control for individual differences in participants’ credit scores and debt literacy (t = 3.65, p < .001). Additionally, the effect was not driven by reduced engagement in the search; even when we controlled for how long participants spent on the survey as a whole, the effect of present bias on less search remained (t = 7.26, p < .001).

Present bias also had a significant negative effect on choice accuracy (t = 1.95, p < .05). A mediation model (Preacher and Hayes 2008) was consistent with our hypothesis that present-biased consumers choose credit cards with higher fees because they search less extensively. Finally, process evidence suggests the difference in search is driven by the amount of search, not which attributes are searched. Accordingly, present-biased participants searched less for every piece of information, even for low introductory rates and back-loaded fees that might be most appealing to them. Present-biased individuals also were not significantly more likely to choose cards with low introductory rates. This suggests that present bias affects the process through which individuals make credit card decisions, not the weights they place on different attributes.

In Study 2, we demonstrated that the effect is not caused by the unfamiliar display of Mouselabweb, in which information is hidden behind boxes. Neither was it confined to the online Mechanical Turk sample. We sought a sample of 300 participants, some of whom were university students who searched credit cards in the laboratory while they were monitored using a Tobii eye-tracker (n = 52). Others were online participants monitored using Mouselabweb with closed boxes as in Study 1 (n = 248, from Prolific Academic). The rest of the procedure was the same as in Study 1. We coded search as the number of boxes opened for Mouselabweb participants (as in Study 1) and as the number of boxes fixated for eye-tracking participants. Present bias again predicted less search (t = 2.05, p = .041). There was no present bias x sample interaction (t = 0.91, p = .326), suggesting that the relationship was not moderated by the type of search monitoring or sample. In Study 3, we replicated Study 1 with a group of MBA students (n = 185), who scored considerably higher on measures of financial literacy and numeracy, and in many cases had experience working in the financial sector. The results mirrored those in Study 1.

In Studies 4A–4D, we measured the association between time preferences and search in large field surveys of American households (SBI’s MacroMonitor field survey). In each of the four field surveys, there were over 4,000 American households participating. Respondents reported how many resources they searched in the past year when choosing financial products. They also responded to a series of intertemporal choices between smaller-sooner and larger-later amounts. From these choices, we calculated present bias for each participant. We then analyzed whether present bias predicted less search. There was a significant negative correlation between present bias and search, such that present-biased respondents searched significantly less than more patient respondents (r = −0.18, p < .05). Though the effect size was fairly small, these results suggest that present biased consumers search less.

Every choice depends upon the selection of a decision strategy, which involves the expenditure of effort now for better outcomes later. Our results suggest that time preferences do not lead people to search different pieces of information nor does it influence the
weight given to each attribute. Rather, they lead to less extensive search, causing people to terminate search more quickly.

**An Under-Shooting Bias in Asymmetric Resource Problems**

EXTENDED ABSTRACT

Suppose that you are one of many competitors choosing between two options. One option has more resources than the other, and the resources from each option will be divided equally among everyone who chooses it. Which option would you choose? A myriad of important decisions involve these basic characteristics: one option contains more resources than the other (e.g., more customers, more jobs, etc.), and the greater the number of competitors choosing that option, the fewer the resources available to each. In order to maximize your own outcome, you have to think about the strategies of others.

We refer to such decision problems as asymmetric resource problems. To mimic this type of problem, we have developed a Two-Account Game. In the game, N players choose between a large account containing \( L \) and a small account containing \( S \) (\(< L \)). Players know that everyone must choose independently and cannot swap money afterward, and that the money in each account will be divided equally among those who choose it.

If everyone followed the Nash equilibrium mixed strategy, on average approximately \( L/(L+S) \times N \) players should choose account \( L \). This proportion is an equilibrium because, regardless of account choice, each competitor stands to earn \( S/(L+S) \times N \), and no competitor has an incentive to deviate and choose a different account.

Behaviorally, however, people may not adopt equilibrium strategies. If the proportion of players choosing the large account exceeds \( L/(L+S) \), then those who chose the large account will stand to earn less than those who chose the small account; we term this outcome under-shooting. On the other hand, if the proportion of players choosing the large account is below \( L/(L+S) \), then those who chose the small account will stand to earn less than those who chose the large account; we term this outcome under-shooting.

We conducted multiple studies to test whether people exhibit any biases in the game, and find a systematic under-shooting bias. In Study 1, involving real money, a group of online workers chose between one account containing $55 and one containing $45, knowing that the money in each account would be divided equally among those who chose it. We found a significant under-shooting bias: only 42.0% of participants chose the large account, a proportion not smaller than the Nash-equilibrium benchmark of 55%, but also smaller than 50%. Study 2 tested whether people would still exhibit the under-shooting bias if they played many rounds of the game. Specifically, a group of Mechanical Turk participants were asked to choose between one account containing $70 and one containing $55, and to repeat the same game for 25 rounds without feedback. We found systematic under-shooting both in the first round and across all the rounds.

Study 3 replicated the result in a more contextually-rich setting and with different levels of resource asymmetries between the two options. Participants were asked to imagine that he/she was one of 20 ice cream vendors who planned to go to one of two outdoor events tomorrow to sell ice cream. The more vendors that went to a certain event, the less profit each vendor could make. However, there would be more customers in one event than in the other. Participants were randomly assigned to one of three asymmetry levels (number of customers in the large event versus number of customers in the small event): 5500 vs. 4500, 7000 vs. 3000, and 8500 vs. 1500. In all conditions, fewer participants went to the large event than the proportion of customers in the large event.

Study 4 explored a boundary condition of the under-shooting bias. One potential mechanism for the bias is mistaken beliefs about the strategies of others. If that were indeed the case, then manipulations that increase participants’ understandings of how others form strategies could potentially mitigate the bias. Based on prior work showing that making others more vivid leads to improved perspective-taking, we manipulated the vividness of other players to examine whether this manipulation would mitigate the under-shooting bias. Thus, Study 4 had two between-subjects conditions: control and vividness. All participants were asked to imagine that they were playing the two-account game with 19 acquaintances. In the vividness condition, participants were asked to write down the first names of the 19 acquaintances and then choose the account. In the control condition, participants were not asked to do so. The results showed that the under-shooting bias appeared in the control condition but disappeared in the vividness condition, suggesting that vividness manipulation mitigated under-shooting and led participants to make choices consistent with the equilibrium prediction.

Resources are limited, and competition is an important part of life; people apply for a limited number of jobs and compete for a limited number of customers. While extensive research has studied resource-competition problems in which the allocation of resources is either symmetric or unknown, little work has been done on the general class of problems that involve asymmetric allocations. This research fills this gap by developing a simple yet versatile Two-Account Game to study the asymmetric resource problem. We found the asymmetry to be critical for behavior—while extant work has yielded little evidence of systematic deviations from equilibrium strategies, we found a significant under-shooting bias across different populations, different domains, and different levels of resource asymmetries. Additionally, we show that this bias vanishes if the competitors in the game are made vivid.

SESSION OVERVIEW

Scarcity pervades many corners of this world. Nearly 700 million people live in extreme poverty (World Bank 2018) and resources such as clean water and electricity are inaccessible to more than 10% of the world population (WHO and UNICEF 2014; UNDP 2014). Even relatively wealthy individuals can feel like they lack resources because of changes in the environment. Fluctuating economic conditions and widening income disparities (Alvaredo et al. 2018) can impact their subjective interpretation of their own condition by shifting what is considered a desirable standard (Cannon, Goldsmith, and Roux 2019; Sharma and Alter 2012). Despite the pervasiveness of scarcity, consumers experiencing scarcity have often been ignored in academic research (Smith 2005; Chakravarti 2006) and there remain many unanswered questions about how consumers experience and cope with scarcity. This session aims to understand how people cope with the experience of scarcity and how such coping processes spill over to other decisions such as product choices.

Salerno and Escoe begin the session by examining how people directly cope with the experience of scarcity by engaging in emotion regulation. The authors argue that people regulate negative emotions arising from scarcity with emotional benefits of pride. This leads people experiencing scarcity to systematically value pride more.

The next three papers examine indirect ways of coping with scarcity via attitude expression and choice. Yang, Kim, and Adaval point to attitude expression as an indirect way of coping with the experience of scarcity. The authors show that consumers experiencing scarcity express attitude more extremely because they have a heightened need to be heard.

Tezer, Roux, and Goldsmith show that the process of coping with scarcity can spill over to product decisions. The authors argue that the experience of scarcity threatens social self-esteem and people cope with this threat by acquiring products offering self-improvement benefits. This leads people experiencing scarcity to systematically prefer self-improving products.

Finally, Wu, Zhu, and Ratner demonstrate that people use choice switching to cope with the experience of scarcity. The authors argue that scarcity increases arousal which in turn intensifies the feeling of uncertainty in choice. This leads people to switch choice from an initially more-preferred to a less-preferred option.

The papers in this session collectively raise and answer the question: How do people cope with scarcity and how do such coping processes spill over to other decisions. In line with the conference theme of becoming wise, this session aims to expand wisdom by focusing on the under-heard segment of consumers and demonstrating how their decisions differ from the major segment. As the four papers in this session present a coherent set of novel findings about consumer responses to scarcity, we believe this session will appeal to a broad audience, including researchers interested in scarcity, affect, and attitude as well as those interested in public policy.

Resource Scarcity Enhances the Value of Pride

EXTENDED ABSTRACT

Resource scarcity occurs from a discrepancy between one’s current level of resources and a more desirable reference point (Cannon, Goldsmith, and Roux 2019). Prior research has shown that resource scarcity can be accompanied by negative feelings such as stress, physical pain, and decreased life satisfaction (Chou, Parmar, and Galinsky 2016; Griskevicius et al. 2013; Sharma and Alter 2012). These negative feelings are from an underlying loss of control brought on by scarcity (Cannon et al. 2019). However, the literature to date has not considered how consumers seek to regulate such feelings. We investigate this issue.

Two approaches have been documented for how consumers regulate their feelings. One approach follows the classic principle that emotion regulation motivates behavior towards feeling good (Cohen, Pham, and Andrade 2008). This is known as hedonic emotion regulation (Tice and Baumeister 2000). Another more recent approach assumes that emotion regulation does not always motivate behavior geared towards feeling better per say, but rather, towards providing emotional benefits to salient goals (Coleman and Williams 2013). This is known as instrumental emotion regulation (Tamir 2016). Together, these two approaches suggest that consumers may value different positive emotions depending on what goals are currently salient.

We propose that when resource scarcity occurs, consumers favor regulating their negative feelings by engaging in instrumental rather than hedonic emotion regulation. Specifically, consumers may forego happiness and instead value positive emotion that helps address the goal to regain control brought on by scarcity. We propose that pride is uniquely suited to serve this function. Pride is a self-conscious emotion associated with achievement and successful self-regulation (Tracy and Robins 2007) and its experience creates an emotion-based inference of being self-disciplined (Salerno, Laran, and Janiszewski 2015). Thus, we hypothesize that resource scarcity enhances the value of pride owing to its ability to compensate for the loss of control instantiated by scarcity. Four studies test this prediction.

Study 1 examined the effect of resource scarcity on the perceived usefulness of different emotions. We used a single factor (mindset: control, scarcity, abundance) between-subjects design. A writing task manipulated participants’ mindset. Participants in the scarce (abundant) condition wrote about a time in which resources were scarce (abundant). The control condition wrote about a typical...
day. Next, participants saw 12 emotions and categorized them into two boxes according to which were most (least) useful. An effect of mindset was found on the propensity to categorize pride as most useful ($\chi^2 = 7.74, p = .02$). Participants in the scarcity condition categorized pride as most useful (79.3%) more than participants in the abundance (57.6%) and control condition (59.4%).

Study 2 tested the motivation to engage in hedonic versus instrumental emotion regulation by comparing the persuasiveness of an ad featuring either a happiness-based or pride-based emotional appeal. We used a 2 (mindset: control vs. scarcity) x 2 (emotional appeal: happiness vs. pride) between-subjects design. Mindset was manipulated as in study 1. Next, participants examined a gym ad that either discussed a happiness or pride emotional appeal and indicated its persuasiveness. An interaction emerged between the mindset and emotional appeal factors ($F(1, 195) = 4.24, p = .04$). In the pride condition, participants were more persuaded in the scarcity than control condition ($p = .04$). Conversely, in the happiness condition, participants did not differ in their reported persuasiveness ($F < 1$).

Study 3 used a measurement-of-mediation approach to provide process evidence by measuring participants’ motivational orientations. If people value pride more owing to its ability to compensate for scarcity’s underlying loss of control, then they should report being more motivated to become better individuals (i.e., instrumental emotion regulation) than to feel better (i.e., hedonic emotion regulation). We used a single factor (mindset: control vs. scarcity) between-subjects design. We manipulated mindset via a newspaper article that either discussed zoos (control condition) or the planet’s scarce resources (scarcity condition). Next, participants indicated whether they currently held an instrumental (vs. hedonic) motivational orientation. Finally, participants watched and evaluated a pride-inducing commercial. Participants in the scarcity condition reported that their motives were more instrumental in nature ($t(182) = -3.19, p = .01$) and had higher evaluations of the commercial ($t(182) = -2.15, p = .03$). Furthermore, the effect of scarcity on commercial evaluation was mediated through motivational motivation (indirect effect 95% CI: 0.56 to 4.87).

Study 4 used a moderation-of-process approach to provide process evidence by manipulating whether participants could affirm personal values that bolster against threats to the self (i.e., self-affirmation; Steele 1988). If our theorizing regarding the mechanism by which resource scarcity enhances the value of pride is so, then this effect should persist (attenuate) in the absence (presence) of self-affirmation. We used a 2 (mindset: control vs. scarcity) x 2 (self-affirmation: no affirmation vs. affirmation) between-subjects design. Mindset was manipulated as in study 1. Next, participants ranked the importance of various personal values. In the affirmation (no affirmation) condition, participants wrote about the value most (least) important to them. Lastly, participants were told they could watch a new two-minute ad campaign highlighting the pride of their university. However, in order to watch the video, participants were first asked to complete another task in which they evaluated products, such that for every product they evaluated, they could watch two seconds of the video. An interaction emerged between the mindset and self-affirmation factors ($F(1,398) = 4.46, p = .035$). In the no affirmation condition, participants were more motivated (i.e., evaluated more products) in the scarcity than control condition ($p = .01$). However, in the affirmation condition, participants were similarly motivated in the scarcity and control condition ($F < 1$).

This research contributes to the resource scarcity literature by documenting the affective, rather than cognitive, behavioral responses to scarcity. It also contributes to the emotion regulation literature by identifying one factor (i.e., resource scarcity) that determines when instrumental vs. hedonic emotion regulation takes precedence. Finally, this research has direct implications for consumer well-being as resource scarcity is a pervasive phenomenon in our everyday lives.

**My Voice Also Counts: Financial Scarcity Shapes Attitude Extremity Through a Heightened Need to be Heard**

**EXTENDED ABSTRACT**

Extreme attitudes are powerful because they have a disproportionately large impact on shaping the overall opinion of the crowd. Media coverage of extreme views polarizes public attitudes (Powell 2011). For instance, exposure to news on terrorism increases prejudice towards outgroup members (Das et al. 2008), and consumption of news showing extreme political views polarizes viewers’ political stance (Jones 2002). Even in marketing, the extremity of product reviews shapes decisions of potential buyers as consumers often base their purchase decisions on such reviews (Mudambi and Schuff 2010). Such wide ranging consequences raise the need to understand causes of attitude extremity. This research proposes that one cause of extreme attitudes is scarcity and investigates why.

We propose that financial scarcity, a state of feeling financially worse-off than a salient standard (Sharma and Alter 2012), increases attitude extremity due to a heightened need to be heard. Because people experiencing financial scarcity are often deprived of the chance to make themselves heard, they are likely to have a greater need to be heard. Indeed, past research has shown that authorities give less consideration to people experiencing financial scarcity (Narayen et al. 2010); polling agencies grant a smaller weight to opinions of the poor (Birch and Moss 2017); and the opinions of such individuals are often not welcomed by others (Lott 2002). Since feeling significant is a fundamental human need (Kruglanski et al. 2017), we posit that financial scarcity will increase the need to be heard. One way of being heard is by expressing attitudes more extremely. Compared to moderate attitudes, extreme attitudes capture more of the audience’s attention and are more likely to be noticed by others (Fiske 1980). Hence, financial scarcity increases attitude extremity in an effort to satisfy the heightened need to be heard.

Study 1 (N = 1,612) tests the hypothesized relationship between financial scarcity and attitude extremity by measuring financial condition and attitude extremity. Participants first indicated their opinion on nine social/political issues such as a ban on plastic products and farm subsidies along 11-point bipolar scales anchored at -5=Strongly oppose, 0=Neutral, and 5=Strongly support. Annual household income was used as a proxy for financial scarcity (Johar, Meng, and Wilcox 2015; etc.). Attitude extremity was measured by taking the absolute score of deviation from the midpoint and summing them. As hypothesized, a simple linear regression model revealed the household income level to be a significant negative predictor of attitude extremity (β = -0.41, p = .005). This relationship remained significant (β = -0.58, p = .007) even after controlling for factors such as age, education, and emotional expressivity which have been shown by past research to impact attitude extremity (De Jong, Steenkamp, Fox, and Baumgartner 2008; Hamilton 1968). This finding suggests that people who are likely to experience financial scarcity (i.e., earning low-income) express relatively more extreme attitudes.

Study 2 (N = 274) tests underlying mechanism of the hypothesized effect by employing a single factorial between-subjects design (financial scarcity: scarcity vs. abundance). Financial scarcity was manipulated by having participants write about a situation in which they felt financially worse-off or better-off compared to others in the
same community (Sharma and Alter 2012). Attitude extremity was measured as in Study 1. Following this, participants’ state need to be heard was assessed using 3 items (e.g., I have a strong desire to be heard). As predicted, participants in the scarcity (vs. abundance) condition expressed more extreme attitudes ($M_{scarcity} = 23.33, M_{abundance} = 21.92; p = .07$) and had a stronger need to be heard ($M_{scarcity} = 7.05, M_{abundance} = 6.67; p = .06$). Importantly, a mediation analysis revealed that a heightened need to be heard mediated the relationship between financial scarcity and attitude extremity (95% CI [.018, .455]), whereas the reverse mediation was not significant (95% CI [-.001, .117]).

Study 3 ($N = 229$) addresses an alternative account by increased arousal. One could argue that scarcity increases arousal which then leads participants to respond more extremely. If this were true, participants would respond more extremely to all issues as well as to statements that varied in extremity. However, if participants indeed have an extreme attitude, they would agree more strongly only to extreme statements, but not to moderate statements. Study 3 tested this logic by employing a 2 (financial scarcity: scarcity vs. control) × 2 (statement extremity: extreme vs. moderate) mixed design with the first factor manipulated between subjects and the second factor manipulated within subjects. Participants in the scarcity condition wrote about when they felt financially worse-off compared to others whereas participants in the control condition wrote about watching TV. Next, we measured participants’ mood state using PANAS (Watson, Clark, and Tellegen 1988). Attitude extremity was then assessed by measuring the extent to which participants agree with extreme statements (adapted from Webber et al. 2018). Specifically, participants read five extreme statements and five moderate statements related to the same set of consumer issues (e.g., personal information collection) and indicated how much they agreed with each statement on a 7-point scale (1=Strongly disagree, 7=Strongly agree). Mood state did not differ between the two conditions ($p > .30$). As predicted, there was an interaction effect between financial scarcity and statement extremity ($p = .09$). On extreme statements, participants in the scarcity condition indicated stronger agreement ($M_{scarcity} = 4.19, M_{control} = 3.86; p = .06$), whereas participants in the scarcity condition ($M_{scarcity} = 4.41$) were not different from those in the control condition ($M_{control} = 4.52$) in their agreement on moderate statements ($p = .44$). Among the participants in the control condition, there was a significant negative correlation between standardized annual household income level and agreement on extreme statements ($\beta = -0.19, p = .03$) as evidenced previously in Study 1.

To summarize, we show that financial scarcity heights people’s need to be heard, which in turn increases attitude extremity. The present research adds to our understanding of financially deprived individuals who are often under-heard: Specifically, what makes people experiencing financial scarcity express their opinion in such an extreme manner.

Reminders of Resource Scarcity Decrease State Social Self-esteem and Increase the Desire for Self-Improvement Products

EXTENDED ABSTRACT

We draw from previous research demonstrating that reminders of resource scarcity promote the desire to advance one’s own welfare (Roux, Goldsmith and Bonezzi 2015) to offer the novel prediction that reminders of resource scarcity will increase consumers’ interest in and willingness-to-pay for products offering self-improvement benefits. We further propose that this occurs because reminders of resource scarcity threaten consumers’ state social self-esteem, or one’s concerns about how they are perceived by others (Heatherton and Polivy 1991). Indeed, experiences of scarcity (e.g., poverty) can be judged harshly by others (Olson et al. 2016) and have been shown to negatively impact self-esteem (Chaplin, Hill, and John 2014). Since people tend to attempt to repair their self-esteem when it is threatened (Crocker and Park 2004; Tesser 2000), products offering self-improvement benefits offer consumers exposed to reminders of resource scarcity a mean to repair their social self-esteem, as they “facilitate bettering some self-relevant aspect of the self, including personal attributes or performance in domains important to the self” (p. 403; Allard and White 2015).

We tested our predictions in five experiments. Experiments 1A and 1B tested whether reminders of resource scarcity increase willingness-to-pay (WTP) for products offering a self-improvement benefit. In Experiment 1A ($N = 111$), scarcity was first manipulated by asking participants to list things they would be unable to do if certain resources were unavailable (e.g., water; Roux et al. 2015), whereas those in the control condition were asked to list activities that they could do with the same resources. Next, participants reported their WTP for a sleeping aid product (Allard and White 2015). Results revealed that scarcity increased WTP ($M_{scarcity} =$6.26 vs. $M_{control} =$5.19; $p = .03$). Experiment 1B ($N = 170$) replicated and extended the results of experiment 1A using a different scarcity manipulation and a consequential choice task (adapted from Becker, DeGroot and Marschak 1964). First, participants in the scarcity condition were asked to recall times when they felt resources were scarce, whereas those in the control condition were asked to list activities they did in the past week (Roux et al. 2015). Next, participants were presented with a set of Post-it notes for which self-improvement benefits were either highlighted or not (adapted from Allard and White 2015). WTP was assessed using 20 binary choices where participants had to indicate their preference between receiving the product or a certain amount of money ($0.10-$2.00 in $0.10 increments). Participants were instructed that the computer would randomly select one of their choices at the end of the experiment and they would receive the option selected. A two-way ANOVA revealed an interaction between scarcity and benefits ($p = .01$). When self-improvement benefits were highlighted, scarcity increased WTP ($M_{scarcity} =$0.69 vs. $M_{control} =$0.46; $p = .02$), but no significant difference was observed when these benefits were not highlighted ($M_{scarcity} =$0.42 vs. $M_{control} =$0.54; $p > .2$).

Next, experiment 2A ($N = 116$) tested whether reminders of resource scarcity negatively affect state social self-esteem. Participants first completed the same episodic recall manipulation (Roux et al. 2015) as in experiment 1B. Next, all participants completed the 20-item State Self-Esteem scale (Heatherton and Polivy 1991), which assesses social, performance, and appearance self-esteem. Results revealed that while scarcity negatively impacted social self-esteem ($M_{scarcity} =$4.77 vs. $M_{control} =$4.52; $p = .03$), no significant differences were found for performance ($M_{scarcity} =$5.10 vs. $M_{control} =$5.27; $p = .2$) nor appearance ($M_{scarcity} =$4.28 vs. $M_{control} =$4.62; $p = .2$) self-esteem.

Experiment 2B ($N = 240$) tested whether social self-esteem mediates the effect of scarcity on WTP for a self-improvement product. Participants first completed a financial deprivation (vs. abundance) manipulation where they had to recall a situation in which they were financially worse off (vs. better off) in comparison to peers around them (Sharma and Alter 2012). Next, participants reported their WTP for the same sleeping aid product (Allard and White 2015) as in experiment 1A, and completed the state social self-esteem subscale (Heatherton and Polivy 1991) from experiment 2A. The order of the WTP and social self-esteem measures was counterbalanced and did not impact the results. Results first revealed that scarcity negatively
impacted social self-esteem ($M_{Depri} = 4.44$ vs. $M_{Abun} = 4.89$; $p = .02$). Results further showed that scarcity increased WTP ($M_{Depri} = 5.40$ vs. $M_{Abun} = 4.16$; $p = .02$). Importantly, social self-esteem mediated the effect of scarcity on WTP ($95\% CI = [0.03; 0.61]$).

Prior work has shown that, when self-esteem is threatened, people tend to prefer solutions that allow them to feel better in the immediate (e.g., indulging) over pursuing their longer term goals (e.g., self-regulation; Crocker and Park 2004). Experiment 3 ($N = 334$) thus tested whether reminders of resource scarcity increase preferences for self-improvement products that offer more immediate benefits over ones that operate over a longer period of time. Participants first completed the same episodic recall manipulation (Roux et al. 2015) as in experiments 1B and 2A. Next, participants reported their willingness-to-buy a sleeping aid smartphone application, which was framed as offering either immediate or longer-term benefits. Finally, participants completed the state social self-esteem subscale (Heatherton and Polivy 1991) used in experiments 2A and 2B. A two-way ANOVA first revealed a marginal interaction between scarcity and benefits ($p = .07$). When self-improvement benefits were immediate, scarcity increased trial intentions ($M_{Scar} = 3.84$ vs. $M_{Cont} = 3.13$; $p = .02$), but no significant difference was observed when these benefits were longer-term ($M_{Scar} = 3.32$ vs. $M_{Cont} = 3.38$; $p = .8$). Next, a two-way ANOVA found only a main effect of scarcity on social self-esteem, such that scarcity negatively impacted social self-esteem ($M_{Scar} = 4.90$ vs. $M_{Cont} = 5.86$; $p < .001$). Importantly, a mediated-moderation analysis ($95\% CI = [0.05; 0.34]$) revealed that social self-esteem moderated the effect of scarcity on trial intentions when the self-improvement benefit was immediate ($95\% CI = [0.04; 0.42]$), but not when it was longer-term ($95\% CI = [-0.65; 0.41]$).

In summary, across five experiments, we demonstrate that reminders of resource scarcity decrease consumers’ state social self-esteem, which in turn increase their interest in and willingness-to-buy products offering self-improvement benefits, especially when the benefits are immediate (vs. longer-term). Although further research is necessary to fully understand the boundaries of these effects, this research provides an important step towards a better understanding of the specific desires that are instantiated in response to reminders of resources scarcity and their consequences.

### Impact of Product Supply Level on Choice Switching

#### EXTENDED ABSTRACT

Consumers often choose between alternatives for which they have close preferences. These choices can be as small as which candy to purchase, to big decisions such as which house to buy. Prior literature shows that a scarce (vs. abundant) product supply leads consumers to include more of their favorite when they are choosing multiple items at a time (Zhu and Ratner 2015). But this research does not examine the effect of product supply on product choices when consumers are choosing between close alternatives in a single-choice context. The primary objective of this research seeks to fill this gap by examining how product supply scarcity impacts the choices consumers make when they are choosing among close alternatives.

Prior literature suggests that scarcity induces arousal (Cialdini 2009; Zhu and Ratner 2015), and arousal intensifies affect (Gorn, Pham, and Sin 2001; Paulhus and Lim 1994). We build on this prior research, and predict that a scarce (vs. abundant) product supply increases consumers’ likelihood of choosing the a priori less-referred option when consumers are choosing among close alternatives (i.e., consumers have a priori close preferences for alternatives in a choice set). We suggest that consumers feel uncertain about their relative preferences in this decision context. When they are faced with a scarce (vs. abundant) product supply and therefore a heightened arousal, this feeling of uncertainty will be intensified (Gorn et al. 2001). Such stronger feeling of uncertainty under product supply scarcity (vs. abundance) will lead consumers to become more likely to switch their choices from the initially more-preferred option to the initially less-preferred option.

Four studies tested our predictions. Study 1 ($N = 191$) showed that when consumers are choosing among close alternatives, a scarce versus abundant product supply increases their choice switching behaviors. Participants first rated their liking towards gift cards from eight apparel retailing stores. To operationalize liking closeness, we ranked each participant’s preferences for these gift cards and created four pairs of gift cards representing strong to close pairs (favorite vs. least favorite; 2nd vs. 7th liked; 3rd vs. 6th liked; 4th vs. 5th liked). We then manipulated the supply level of the gift cards (scarce vs. abundant), and asked participants to choose one option from each pair. As predicted, we found a significant interaction between supply level and liking closeness ($p = .025$). In strong pairs, participants in both supply level conditions predominately chose the a priori more-preferred gift card ($ps > .32$). However, when choosing between close alternatives, participants who were faced with a scarce (vs. abundant) supply level of gift cards became significantly more likely to switch and choose their initially less-preferred option ($p = .03$).

Study 2 ($N = 239$) measured the feeling of uncertainty to directly test its mediating role. Similar to the procedure of study 1, we asked participants to choose between two types of candies that they had close preferences for. We manipulated supply level by telling participants that we either had limited quantities (scarcity condition) or large quantities (abundance condition) of the candies. As predicted, participants who were faced with a scarce (vs. abundant) candy supply were significantly more likely to switch and choose the a priori less-preferred candy ($p = .003$). We also found evidence for the uncertainty account, and showed that feelings of uncertainty mediated the relationship between supply level and choice switching behavior ($95\% CI = [-0.401, -.025]$).

Study 3 ($N = 698$) further tested the process of arousal by directly manipulating it. We predicted that when participants’ arousal was experimentally heightened, the effect of product supply on choice switching should attenuate, such that participants in the abundance condition would be as likely to switch as participants in the scarcity condition. As predicted, we found a significant interaction between supply level and arousal ($p = .028$). When arousal was not elevated (control condition), participants in the scarcity (vs. abundance) condition were significantly more likely to choose the a priori less-preferred option ($p = .003$), replicating findings in studies 1 and 2. However, when participants’ level of arousal was increased by presenting the survey on a bright survey background, choice switching behavior did not differ between the abundance and scarcity conditions ($p = .71$). In addition, we found that feelings of uncertainty mediated the relationship between supply level and choice switching in the control condition ($95\% CI = [.06, .26]$) but not in the arousal condition ($95\% CI = [.12, .10]$).

Study 4 ($N = 217$) generalized the results to a broader sense of scarcity. In the scarcity (vs. abundance) condition, we asked participants to read an article about the draining (vs. rich) supply of some essential natural resources, and then to write about the influence of such phenomenon on their personal lives. We also included a control condition to test the driving force of the effect. Replicating the findings in prior studies, we found that participants in the scarcity condition were more likely to choose the a priori less-preferred option than those in the abundance ($p = .004$) or the control conditions ($p = .021$).
The likelihood of choosing the a priori less-preferred option did not differ between the control and abundance conditions. These results suggested that the effects on choice switching were driven by the scarcity, rather than the abundance, manipulation.

To summarize, we find that a scarce (vs. abundant) product supply increases consumers’ likelihood of choosing the a priori less-preferred option when they choose among close alternatives. We find evidence for the arousal and affect intensification account, and show that the effect is mediated by feelings of uncertainty and moderated by manipulating arousal. The present research contributes to literature on scarcity and decision making, and have practical implications for individual decision makers, managers and policy makers.

SESSION OVERVIEW  
The U.S. installed base of smart speakers has hit 66 million in 2018 with 252 million U.S. adults using voice-assistants in their homes or cars (CIRP, 2019). These voice-activated devices only respond when summoned, and consumers usually talk to them using imperative language. Often, the responses coming from voice-activated devices responses can be robotic. Thus, information gathered and decisions made through a voice-activated devices are becoming more and more prevalent. In fact, anthropomorphic assistants may be able to offer an intriguing route to “becoming wise.” Transforming our digital interactions into interpersonal experiences may be one way to calibrate our understanding of our knowledge when we access information online and our preferences when we make downstream decisions based on it.

Consumer behavior research has long examined the nature of consumer-object interactions (e.g., Fournier 1998), but these considerations become more complex and the consequences more profound when the objects we interact with are embedded with the unprecedented functionality as these voice-activated devices provide- allowing us to communicate, shop, consume media, and even monitor our health. Accordingly, the shift to these kind of devices presents consumer behavior researchers with an opportunity for academic research that is not only theoretically important, but that is also rife with timely substantive implications.

Our special session addresses this opportunity by exploring consequences stemming from a broad range of interactions with voice-activated devices and focusing on how the nature of the communication with them may affect information processing, judgements and downstream choice. We demonstrate that these device interactions can influence (1) the perceived accuracy of feedback coming from those devices when real-vocal-sound (versus synthesized-vocal-sound) is in use (Sayin and Krishna), (2) how likely consumers are to express frustration and aggression when interacting with female (versus male) AI (Hadi and Block), (3) how anthropomorphic “smart” assistants (vs. a non-anthropomorphic assistant) lead consumers to believe that they themselves are less smart (Hamilton, Ward, and Yao), and (4) how language accommodation to an imperative form of speech (paper 4). All papers are in advanced stages of completion with multiple studies run.

The progressive approaches and novel results in this session are sure to induce a lively discussion and are likely to appeal not only to researchers interested in voice-activated devices and the nature of the communication with consumers, but to a broader audience interested in consumer-product interactions and consumer interactions with technology more generally.

You Can’t Be Too Polite, Alexa! Implied Politeness of Mechanized Auditory Feedback and Its Impact on Perceived Performance Accuracy

EXTENDED ABSTRACT  
People interact daily with a variety of technical devices. For example, fitness trackers provide feedback on people’s progress regarding their daily activity goals. The way the information between the device and humans is shared affects the strength of the human-device relationship. Hence, product designers try to design the messages provided by such devices in a more personable and relatable way; such as Apple’s Siri use a human voice to communicate with users.

Prior research shows that anthropomorphism can make products more personable and lead consumers to think of the device in social terms (e.g., Gray, Gray, & Wegner, 2007). Anthropomorphism also improves likeability of a product, product preference, satisfaction with the product, product loyalty, and brand love (Aggarwal & McGill, 2007; Chandler & Schwarz, 2010; Rauschnabel & Ahuvia, 2014). Prior literature mainly examines how incorporation of human-like elements impacts the “hedonic appeal” of a product. We focus specifically on consumers’ perception regarding “product performance” of technical devices – its “utilitarian appeal”; we do so within a context where the product provides performance feedback to consumers. We explore whether making technical devices (e.g. running devices) sound more human, affects how consumers perceive the performance of the devices.
Our hypotheses are mainly built upon Brown and Levinson’s politeness theory (1987) which suggests that people inflate performance evaluations when they need to give feedback, in order to avoid any negative emotional reaction from the other person. We argue that the more the device is anthropomorphized (through use of different vocal sounds), the more it is expected to follow social norms – behave politely. We recorded and processed human sounds in a studio to simulate synthesized sound. We equated the volume, pitch, and speed of the sounds. Synthesized vocal sounds usually lack the intonation of natural human speech. As such, real-human-vocal-sound (vs. synthesized-vocal-sound) will be perceived as more human. Thus, in line with politeness theory, whereby people expect inflated performance feedback from others, the accuracy of positive feedback from a device with real-vocal-sound (vs. synthesized-vocal-sound) will be perceived as being lower.

In Study 1, participants (N=98) were asked to imagine they bought a running device and went out for a run. They watched video of the run and were regularly provided feedback (with synthesized-vocal-sound vs. real-vocal-sound) regarding how many miles they had run. An ANOVA showed that perceived accuracy was lower for the real-vocal-sound (M\text{RealVocal}=3.40) versus synthesized-vocal-sound condition (M\text{SynthesizedVocal}=4.42; F(1, 96)=10.06, p<.01).

In study 2, participants received either a negative (or positive) feedback (via synthesized or real-vocal-sound) regarding their performance (how well they did compared to others) after a quiz (N=191). An ANCOVA on perceived accuracy revealed a significant effect of feedback type (F(1,183)=76.54, p<.01) and a significant interaction effect (F(1,183)=18.54, p<.01); the main effect of sound type was not significant (p=.10). When the feedback was positive, participants perceived the feedback with real-vocal-sound (vs. synthesized-vocal-sound) as less accurate (M\text{RealVocalPositiveFB}=4.01, M\text{SynthesizedVocalPositiveFB}=5.06; F(1, 186)=12.29, p<.01). When the feedback was negative, participants perceived the feedback with real-vocal-sound (vs. synthesized-vocal-sound) as marginally more accurate (M\text{RealVocalNegativeFB}=3.15, M\text{SynthesizedVocalNegativeFB}=2.60; F(1, 186)=3.77, p=.05).

In study 3, we used the same design as in Study 2, and additionally explored the effects of sound-type on perceived politeness of the feedback provider (N=111) in a different task. An ANCOVA revealed a significant effect of sound type (F(1,103)=11.67, p<.01) and feedback type (F(1,103)=24.85, p<.01), but not a significant interaction effect (p=.50) on perceived politeness. Participants found real-vocal-sound to be more polite than synthesized-vocal-sound (M\text{RealVocal}=3.96 vs. M\text{SynthesizedVocal}=3.24). Additionally, they found positive feedback as more polite versus negative feedback (M\text{Positive}=4.12 vs. M\text{Negative}=3.09).

Another ANCOVA on perceived accuracy showed a significant effect of feedback type (F(1,103)=43.93, p<.01), and an interaction effect (F(1,103)=6.38, p<.05), but not a significant effect of sound type (p>.80). Simple contrasts revealed a significant effect of feedback type both within the synthesized-vocal-sound (M\text{SynthesizedVocalPositiveFB}=5.11, M\text{SynthesizedVocalNegativeFB}=4.23; F(1, 106)=41.08, p<.01) and real-vocal-sound conditions (M\text{RealVocalPositiveFB}=4.32, M\text{RealVocalNegativeFB}=3.21; F(1, 106)=7.13, p<.01). Examining the interaction further, we found marginally significant effect of sound type both within the positive-feedback (F(1, 106)=3.59, p=.06) and negative-feedback conditions (F(1, 106)=2.95, p=.09).

Finally, we conducted mediation analyses to explore the effect of sound type on perceived accuracy, through perceived politeness, within both feedback conditions. Within the negative-feedback condition, the effect of sound type (t=2.63, p<.05) on perceived politeness was significant. Controlling for sound type, perceived politeness had a significant effect on perceived accuracy (t=2.92, p<.01). Controlling for perceived politeness, sound type no longer had a significant effect on perceived accuracy (t=0.69, p>.40).

These results show that the effect of sound type on perceived accuracy through perceived politeness is moderated by feedback type. When participants received a positive feedback, perceived accuracy of feedback was lower with real-vocal-sound than with synthesized-vocal-sound, through increased perceived politeness. However, when participants received a negative feedback, perceived accuracy of feedback was higher with real-vocal-sound than with synthesized-vocal-sound, again through increase in perceived politeness.

We demonstrate that the desire to make products more human sometimes negatively affects their perceived accuracy - which is critical, because people may not use a device if they do not trust the provided information. Additionally, while the typical method is to pick one voice for one app (which may even be done at a consumer level – e.g., car owners choose a voice for their GPS from a menu), feedback voice for a device could be altered based on what type of feedback needs to be given.

Her Too: Consumers Express Greater Frustration and Aggression with Female Artificial Intelligence

EXTENDED ABSTRACT

Consumers are conversing with artificial intelligence (AI) more than ever before, whether it be with voice-activated assistants (e.g., Alexa, Siri) or customer service chatbots (it is predicted that by 2020, bots will power 85% of all customer service interactions; Hinds 2018). Product designers often try to “humanize” this technology (e.g., imbuing voice-activated assistants with a conversational human voice; presenting chatbots as human-like avatars; Brackeen 2017). Interestingly, the overwhelming majority of voice-activated devices are given a female voice (LaFrance 2016). This disproportion is often attributed to a lack of diversity in the developer community—over 80% of AI developers are male, and implicit (or explicit) biases might lead them to cast female characters in “subservient” roles (Broussard 2018; Simonite 2018). While some industry voices have openly criticized this imbalance (Salinas 2018), surprisingly little research has actually explored how the ascribed “gender” of AI might influence users’ responses.

We address this gap by beginning to explore how the gender assigned to AI can influence consumer responses. Research has found that female service employees are more often targets of expressed frustration and anger from customers than are male service employees, particularly in cases of service failure (Sliter et al. 2010). While AI has no real gender (Adam 1996), it is interesting to explore how the gendered personification of AI may similarly provoke differential responses. Specifically, we hypothesize that consumers are more likely to express frustration and or aggression when interacting “female” (versus “male”) AI assistants. This effect should be especially likely to manifest if the AI assistant performs
inadequately. Further, any elicited frustration should accordingly impair subsequent downstream variables, including participants’ performance on related tasks. Aside from being theoretically interesting, support for these hypotheses would have wide-ranging substantive implications given that people are increasingly relying on AI in their homes (Perez 2017) and in the workplace (Martin 2018).

In study 1 (N = 193), participants interacted with a voice-activated assistant on a mobile phone. The assistant was given a gender-neutral name (“Jamie,” as per pretest results) and the assistant’s assigned gender was manipulated by changing the app settings to use either a male or female voice. Participants were asked to complete various tasks (e.g., visiting various websites) through the assistant via voice commands and all these interactions were audio recorded. Afterwards, a coder blind to our hypothesis transcribed the recorded dialogue and noted any expressions of frustration or aggression (e.g., exasperated sighs, insults) from each participant. Due to the large percentage of participants who did not express any frustration or aggression (70%), we analyzed the data with a Poisson loglinear regression. Results demonstrated that participants were more likely to vocally express frustration and/or aggression throughout the interaction in the female (versus male) assistant condition ($\chi^2 = 4.97, p = .03$).

Study 2 (N = 97) followed the same experimental as in study 1, except participants were asked to accomplish more precise tasks (e.g., asking Jamie to schedule a meeting). At the end of the experience, participants were asked to indicate if they were able to successfully complete the tasks with the assistant. Analysis of the audio recordings again demonstrated that participants were more likely to vocally express frustration and/or aggression with the female (versus male) voice assistant ($p = .03$). However, there was also a significant Assistant Gender x Success interaction on expressed frustration ($F(1, 93) = 3.81; p = .05$): in the female assistant condition, participants expressed significantly more frustration when the app did not successfully perform ($p < .01$). However, in the male assistant condition, there was no difference in expressed frustration cross the two app performance conditions ($p = .76$). Importantly, the assistant’s gender did not impact whether or not the interaction was successful ($p = .99$), suggesting these factors operate independently. However, we manipulate assistant-produced frustration in the next study to more systematically probe this interactive effect.

In study 3 (N = 289) we extend the generalizability of our findings by examining the effect in the domain of chatbots, operationalizing AI gender via the assistant’s name, and examining downstream effects on task performance. The study was a 2(Assistant Gender: male versus female) x 2(Frustration: absent versus present) between-subjects design. Participants were told to imagine they were the office manager of a firm, and they needed to chat with a virtual assistant to accomplish a series of tasks. The chatbot assistant (presented as an avatar pretested to be gender-neutral in appearance) was given either a female (Patricia) or a male (Patrick) name. While the bidirectional dialogue in our previous studies was designed to be as naturalistic as possible, it prevented us from controlling the assistant’s real-time responses to participants’ requests. In the current study we were able to control and manipulate the assistant’s responses. Specifically, we manipulated frustration by having the assistant either respond in a competent way (understanding participants’ inputs immediately) or in a frustrating way (repeatedly misunderstanding participants’ inputs). After the frustration manipulation, participants were told that as the office manager for the firm, they needed to draft an email asking employees not to waste paper. Because previous research demonstrates that when individuals feel frustrated, their performance on tasks suffers (Harold et al. 2016), we expected that when participants interacted with the female (versus male) assistant, frustration should impair participants’ performance. To assess participants’ performance on this task, we considered both the length (objectively measured by word count) and had an independent judge code the emails in terms of effort expended. Analysis results demonstrated an Assistant Gender x Frustration interaction on effort, in terms of both the objective (word count; $p < .01$) and coded measure ($p < .03$). In the female assistant condition, frustration reduced effort expended by participants ($p < .001$ and $p < .001$ respectively). However, in the male assistant condition, there was no difference in expended effort across the two frustration conditions ($p = .49$ and $p = .51$ respectively).

**Minds vs. Machines: Investigating the Role of Anthropomorphism on Knowledge Misattributions in Voice-Activated Consumer Search**

**EXTENDED ABSTRACT**

Consumers increasingly rely on the Internet for information, and they increasingly use voice to access this information; in fact, projections indicate that 50% of all web searches will use voice by 2020 (ComScore 2017). Prior research indicates that searching for and accessing online information causes consumers to become overconfident in their own knowledge—in a sense, to attribute the Internet’s “knowledge” to themselves (Ward 2013a). These misattributions have been shown to increase consumer confidence and lead to increased purchase intentions (Bhargave, Mantanakis and White 2016); however, the miscalibration of knowledge that they produce may be at odds with the broader goal of “becoming wise.” In this research, we investigate how using voice-activated digital assistants to search for information may moderate the misattribution of online information to one’s own memory.

Firms such as Google envision voice activation as a way of making Internet search as frictionless as possible, both by eliminating the need for a physical interface and by encouraging the use of naturalistic language (Schalkwyk et al. 2010). Voice-activated digital assistants such as Google Assistant, Amazon Alexa, and Apple’s Siri encourage naturalistic interactions by transforming Internet search into an interpersonal experience; rather than giving commands to a machine, consumers act as if they are conversing with another mind (e.g., Bellegarda 2013; Cowan et al. 2017). This route to reducing friction may have dual effects on perceptions of personal cognitive ability; although reducing the friction associated with search may increase knowledge misattributions, inserting an intermediary into the mix—particularly one that has been anthropomorphized with human-like characteristics—may reduce these misattributions.

In Experiment 1, we first investigated the effects of friction on knowledge attributions after Internet search. We operationalized friction in terms of device familiarity, with the logic that familiar devices are more likely to become an unobtrusive part of consumers’ daily routines. We measured knowledge attributions using the Cognitive Self-Esteem (CSE) scale, a self-report measure assessing respondents’ beliefs about their own abilities to think about and remember information (Ward 2013b). Device familiarity was measured in the beginning of the experiment in an allegedly unrelated questionnaire. Then, all participants (n = 252) completed a ten-item trivia quiz. Participants in the Google condition used Google to find answers. Participants in the No Google condition answered the questions without outside help. Participants in the Control condition were not given any instructions about how to answer. Finally, participants completed the CSE scale ($\alpha = .93$).
A one-way ANOVA revealed a significant main effect of condition, $F(2, 252) = 3.40, p = .035, \eta^2_p = 0.027$. Participants had higher overall CSE scores in the Google condition ($M = 5.64$) than in both the No Google ($M = 5.29, p_{GvsNG} = .016$) and Control ($M = 5.32, p_{GvsC} = .038$) conditions; CSE scores were not different between the No Google and Control conditions ($p = .846$). We conducted a moderation analysis using hierarchical regression to test our prediction that the effect of Google search on CSE is moderated by device familiarity. The model in the first step was significant, $F(2, 174) = 4.00, p = .016 R^2 = 0.044$, and Google search was the only significant predictor of CSE ($p = .050$). As predicted, the model was significantly improved in the second step when the Google × Device Familiarity interaction term was included, $\Delta F(1, 173) = 10.08, p = .001, \Delta R^2 = 0.053$. The more that participants used their devices as part of their daily routines, the more that using Google results in increased CSE ($p = .010$). These findings suggest that reducing the friction associated with information search may increase levels of knowledge misattribution.

In Experiment 2, we investigated the cognitive consequences of accessing information through voice-activated digital assistants, which may simultaneously reduce friction and introduce another mind into the mix. Participants (n = 127) completed a wine selection task either on their own (Control condition) or using one of two voice-activated digital assistants. Participants in the Machine condition used a voice-activated digital assistant called “Beta Simulator” to find information and offer some clues as to why this might be the case. These analyses revealed the two digital assistants were perceived similarly in terms of their ability to anticipate what one might enjoy ($M_{Mind} = 5.26$ vs. $M_{Machine} = 5.60; p = .038$), and marginally lower than in the Control condition ($M_{Control} = 5.54; p_{MindvsControl} = .051$); there was no difference between the Machine and Control conditions ($p = .996$). These data suggest that using an anthropomorphic voice-activated digital assistant to access online information may undermine the general tendency to attribute the Internet’s “knowledge” to oneself. Exploratory analyses of perceived anthropomorphism (Waytz, Heafner and Epley 2014) offer some clues as to why this might be the case. These analyses revealed that the two digital assistants were perceived similarly in terms of their ability to anticipate what one might enjoy ($M_{Mind} = 4.25$ vs. $M_{Machine} = 4.00; p = .417$), and only marginally differently in terms of their ability to plan their recommendations ($M_{Mind} = 5.47$ vs. $M_{Machine} = 5.60; p = .078$); however, participants perceived the anthropomorphic assistant “Sasha” to be significantly smarter than the non-anthropomorphic “Beta Simulator” ($M_{Mind} = 4.98$ vs. $M_{Machine} = 5.70; p = .011$). It may be that perceiving one’s assistant as “smart” inhibits the tendency to attribute this assistant’s knowledge to oneself.

These data suggest that anthropomorphic assistants may offer an intriguing route to “becoming wise.” Transforming our digital interactions into interpersonal experiences may be one way to calibrate our understanding of our own knowledge when we access information online.

The verbal chameleon effect, and Alexa. An assemblage theory approach.

**EXTENDED ABSTRACT**

Amazon’s Echo (as other voice-activated home devices) is a smart home speaker embedded with artificial intelligence. Dubbed Alexa, Amazon’s Artificial Intelligence has gained popularity in many households. The U.S. installed base of smart speakers has hit 66 million in 2018 (CIRP 2019) with 252 million U.S. adults using voice-assistants in their homes or cars (CIRP 2019). Consumer decisions made through a voice-activated device are becoming more and more prevalent. Alexa only responds when summoned, and consumers usually talk to her using imperative language. Often, Alexa’s responses can be robotic. In this paper, we investigate how language accommodation to Alexa’s commands may affect downstream decisions and behavior.

Chartrand and Bargh (1999) established the basis for the chameleon effect. The chameleon effect is a specific form of synchrony that takes place among dyads rather than within and between groups (for a review, see Chartrand & Lakin 2013). As adults, we engage in mimicry to establish and maintain social relations with others (Chartrand & Bargh 1999). However, the mimicry literature concentrates on its nonverbal aspect. Vocal mimicry (Muir et al. 2016), on the other hand, has received less attention. A related theory in linguistics literature relates to the mechanism underlying verbal mimicry: Accommodation theory (Giles 1973; Gallois, Ogay, and Giles 2005; Koslow, Shamdasani, and Touchstone 1994).

Two crucial theories in the field of linguistic accommodation explore the motivation for verbal imitation. One theory, the interactive alignment model, describes imitative behavior as automatic and uncontrolled (Goldinger 1998; Pickering and Garrod 2004). According to this theoretical framework, every level of linguistic representation is connected within an individual’s mind, as well as interconnected with the listener. This automatic process leads to the activation of the particular linguistic representation used by a speaker in the listener’s mind. However, this potentially automatic process seems to be goal-directed: the speaker modulates social distance by using either converging or diverging speech patterns (Shepard, Giles, and Le Poire 2001).

Convergence, which is of particular interest here, arises when speakers alter their linguistic patterns to adopt styles more like that of their interaction partners (see also: Wisniewski, Mantell and Pfndrescher 2013). Verbal mimicry can even be used strategically to influence the mimickee’s opinion. For example, Tanner, Ferraro, Chartrand, Bettman, and van Baaren (2008) run studies in which, while conducting a product test (e.g. water, snack), the interviewer (in fact a confederate) mirrored the gestures of the participant, and imitated the participant’s comments, as if to verify what he or she said. Importantly, in the control condition, the interviewer spoke a sentence in an equal length to participants’ statement, but none of the words were mimicked. The results provided evidence that participants who were nonverbally and verbally imitated by the confederate provided significantly higher ratings of the products tested than those who were not mimicked.

In our study, we focus on the dyad consumer-Alexa, which is part of the new assemblage theory (Hoffman and Novak 2018). With an aim to understand whether consumers will adapt their language to a machine. This presumably happens automatically and, as accommodation theory suggests, may also be goal-driven. Alexa, positively reinforces speech behavior by providing the answers that the individual is searching. This, in turn, motivates further accommodation by the individual. In this paper, we investigate the
consequences of such linguistic accommodation. We propose three potential outcomes of verbal accommodation: enhanced sense of power, status seeking and motivated pro-social behavior. Talking to Alexa makes people use assertive language, which increases their feelings of power. High power individuals are more persuaded by hard-sell advertising, which emphasizes utilitarian properties of products, hold more favorable attitudes towards a high vs. a low-status product, and show less concern for visible, conspicuous consumption (Rucker and Galinsky 2009). Finally, previous research (Kulesza, Dolinski, Huisman, and Majewski 2014) has found that verbal mimicry, or accommodation, leads to prosocial behavior. A set of three studies tests these ideas.

In these studies, participants worked in individual lab rooms where they were presented with an Amazon Echo dubbed “Computer.” Participants were given a 3-minute practice run. After that, we measured their assessment of the experience on a 7-point scale (1 = Not at all; 7 = Very much). After a short break, participants are given 8 tasks to fulfill with their Echo and told that they would get rewarded by their performance. After that, they had to make different downstream decisions depending on the study. At that point, we measured their level of language accommodation (“I like to accommodate to others during a conversation”, “I like to mimic others during a conversation) and effectiveness communicating with Echo. Individual differences were measured and, importantly, their experience (yes/no) with Alexa and with voice-activated phone systems (type Siri) were recorded.

Study 1: Experience and Language Accommodation (N= 114).
Liking of their Alexa experience: we identify a significant two-way interaction between whether participants had prior experience with Alexa and whether they had experience with other voice-activated systems (F (1, 113) = 6.47, p < 0.05). Participants liked their experience more when they had not interacted with Alexa before but had some experience using voice to operate technology (M = 5.2) compared with when they had not interacted with Alexa and had no prior experience with other voice activated system (M = 4.4) or had prior experience with both (M = 4.5).

The same pattern was identified for language accommodation (F (1,113) = 3.87, p < 0.05) and the perception of communication effectiveness (F (1,113) = 6.73, p < 0.01). As in Muir et al. (2016), the increased speech assimilation due to the novelty (no prior experience with Alexa) but accessibility of the task (prior experience with other voice-operated systems) predicted enhanced perceptions of the communicative effectiveness of the speaker.

We had also asked participants to write a 30 words add about “Computer”. We analyzed it using LIWC and found a significant difference in the summary variable called Clout (refers to the relative social status, confidence, or leadership that people display through their writing or talking): 90 score when they had not interacted with Alexa before vs. 84 when they had F (1, 113) = 4.35, p < .05.

Study 2: Pro-social Behavior (N= 90). The procedure was identical to that of Study 1, but after performing the tasks with Alexa, those that had been able to perform more than 3 tasks, were asked for their propensity to “participate in some kind of volunteer work” (7-point scale: Definitely will not, Definitely will). We again identified a significant two-way interaction between whether participants had prior experience with Alexa and whether they had experience with other voice-operated systems (F (1, 89) = 3.97, p < .05). Participants were more willing to volunteer when they had not interacted with Alexa before but had some experience using voice to operate technology (M= 6.1) compared with when they had not interacted with Alexa or any other voice activated system (M = 4.8) or had prior experience with both (M = 5.3).

Study 3: Status Consumption (N=93). The procedure was again the same as Study 2 but participants were asked to rate (7-point scale: “I would like this ad”) a status-driven ad (“A symbol of status. The Office Pen is designed to attract attention with its extraordinary quality.”) and a non-status driven ad (“A symbol of quality. The Office Pen is designed to perform consistency with its extraordinary quality.”). Then they were asked to provide their WTP (10% to 120% of retail price) of status (e.g. briefcase, silk tie) or non-status products (e.g. sofa, washing machine). We identified again a significant two-way interaction between whether participants had prior experience with Alexa and whether they had experience with other voice-operated systems for liking of status Ad (F (1, 92) = 3.91, p < .05) and overall WTP for status products (F (1, 92) = 3.57, p < .06). In both cases, status was valued more when there was no experience with Alexa but experience with voice-operation (M= 4.35 and 5.40 respectively) compared with when there was no experience with either of them (M= 3.10 and 4.80 respectively).

Taken together, a pattern of language accommodation when talking to Alexa leads to proneness towards pro-social behavior and status seeking when consumers’ experience is new but there is already a sense of what is it to adapt to voice-operated technology.

SESSION OVERVIEW

In this session, we highlight evolving issues of consumer agency that emerge from pervasive technology augmentation. Consumers use technology to augment their lives in multifaceted ways to enhance convenience and improve outcomes. For example, technology enables one to shop better and smarter, allowing one to locate desired products and services and to maximize value: setting alerts for new products, sales and promotions. With mass adoption of consumer artificial intelligence, we now have millions of devices like Amazon-Alexa constantly listening, at the ready to assist: adding to grocery lists, delivering curated daily news and providing weather forecasts. The Apple Watch is constantly monitoring users’ activity, exercise and sleep and nudging consumers to ‘improve’ themselves. And, arguably antithetical to the tenets of meditation, Headspace provides users a meditation dashboard showing daily ‘streaks’, minutes meditated and other such achievements.

With over half of the world’s population interacting with code-driven systems (Anderson, Rainie and Luchsinger 2018:1), the rapid influx of AI into the domain of consumption has been one of the most stunning marketing developments in recent time: “digital life is augmenting human capacities and disrupting cons-old human activities” (Anderson et al 2018:1). Advances in computing have enabled complex algorithms to assist in, and shape, a growing number of consumer activities. Increasingly, AI is quantifying consumers who rely on app enabled dashboards of formerly uncodified, idiosyncratic metrics to measure their health, fitness, skills and efficiency.

Proponents of consumer technology proclaim powerful technological capabilities that are built into their products and services create high levels of consumer engagement. Similarly, consumer researchers investigating consumers’ use of embedded, even ambient technology arrive at conclusions and recommendations that are consistent with the positive potential of technological influence (Hoffman and Novak 2017). By focusing on the benefits, previous market-}

ing scholarship has neglected the ways in which these technologies shape consumer experience and behavior in more problematic ways.

Four papers interrogate the promise and perils of omnipresent technology in consumer life. We offer these presentations in escalating impact of technology on consumer practices: 1) an empirical study of technological augmentation of agentic pursuit of price savings and how the quest for value in exchange may have unforeseen collateral impact, 2) a conceptual overview of dystopian mythologies consumers associate with AI which are largely related to questions of agency, and managerial strategies for mitigating consumer concerns, 3) an empirical investigation of the impact of algorithms and quantification on agency 4) an empirical examination of mandated surveillance through AI in the workplace to enhance workforce efficiency and how differing perceptions of agency arise and make an impact on the effectiveness of the technology deployed. We believe this set of research papers will spark lively conversations about technology and consumer agency.

The Double-Edged Sword of Online Collective Deal Creation

EXTENDED ABSTRACT

U.S. consumers are fond of price promotions with 174 million Americans reported as shopping during 2017’s Black Friday and Thanksgiving sales (National Retail Federation 2017). It should come as no surprise that millions of consumers use the internet to learn about price promotions such as Black Friday sales. BigDeals (pseudonym), a consumer-to-consumer platform (Perren and Kozinet, 2018) devoted to identifying price promotions attracts over 10 million monthly users and describes itself as the leading and most trusted online deal-sharing collective. Consumers use the site to go beyond simply learning about available promotions. Members of BigDeals actively participate in its forums in order to construct what they call “deals.” Deals are opportunities to purchase a product or service at a lower than listed retail price due to a perceived mistake or loophole. Deals are often achieved by combining multiple promotions across channel members: 1) someone might alert the forum to an attractive sale at a retailer, 2) a fellow user may chime in with a free shipping code and 3) another user might indicate which credit card to use to receive additional cash back.

Given that the primary focus of these collectives is the quest to extract the utmost value from market transactions, prior research suggests that these collectives ruthlessly leverage promotional information to maximize value-in-exchange. We find that these deal hunter collectives have defined boundaries on their market behaviors and meticulously self-police in the interest of market concerns beyond the immediate collective. Using a netnographic analysis, we show that in the unique context of a co-creative collective, moral judgment and moral hypocrisy act to limit the behavior of all actors, including those who render judgment but otherwise enact an illegitimate deal. This creates a novel outcome whereby public judgment has a boomerang effect, reducing or eliminating prevalence of illegitimate deals, and thus implicitly forcing judges and the entire collective to behave more ethically. We argue that this effect occurs for two reasons. First, public judgment within a group context may lead the group to define and characterize itself as more moral. Consistent with social comparison (Campbell, 1964; Cialdini & Trost,
1998; Gino, Ayal, & Ariely, 2009) and social identity (Gino, Ayal, & Ariely, 2009; Tajfel, 1982) theories, such morality is then assimilated and mirrored, respectively, within the group. Second, public judgment of others within a collaborative collective setting necessarily limits what is discussed. Condemning those that post unethical ideas results in less discovery and creation of unethical deals within the collective. Since the collective is much better than one individual at discovering and creatively developing deal opportunities of any form, such condemnation has the unintended effect of limiting everyone's, including judges', ability to identify, construct, and enact illegitimate deals.

Our investigation reveals a novel byproduct stemming from previously demonstrated moral hypocrisy effects (Batson, Kobrynowicz, Dinnerstein, Kampf, & Wilson, 1997; Monin & Merritt, 2012). We show that when hypocrical judgment occurs in a co-productive collective environment the effect extends not only throughout the collective, but importantly indirectly limits the hypocrite's own opportunities. This is noteworthy because moral hypocrisy, by its very nature, rests on a consumer’s ability to rationalize their own unethical behavior better than that of others. Additionally, consumers are prone to forget their own misdeeds (Kouchaki & Gino, 2016) as well as moral rules they have broken (Shu & Gino, 2012; Shu, Gino, & Bazer, 2011). The ability of a collective to reflect and strengthen a consumer’s espoused moral standards in the face of natural predisposition to rationalize their own unethical behavior is significant.

While research shows that emulating (Campbell, 1964; Cialdini & Trost, 1998; Gino, Ayal, & Ariely, 2009) or identifying (Gino, Gu, & Zhong, 2009) with a group can help consumers uphold ethical standards, this is not always the case. Consumers are known to limit their own unethical response only when an out-group member is present (Gino, Gu, & Zhong, 2009) or when acting ethically is salient (Gino, Ayal, & Ariely, 2009). Groups are also known to diffuse responsibility, providing cover for immoral behavior that individuals may otherwise refrain from doing (Diener, Fraser, Beaman, & Kelem, 1976; Latane, 1981). Our findings provide insight into an additional, and possibly more general, mechanism through which groups can uphold ethical behavior. The effect of reflected moral hypocrisy is also notable in that it extends to protect out-group members, who are often exploited at the expense of an in-group (Gino, Ayal, & Ariely, 2009; Opotow, 1990; Reed & Aquino, 2003). While moral responsibility is an element of brand community, it is an 'in-group' behavior (Muniz & O’Guinn, 2001). Some brand communities behave in a socially responsible manner, but this is an idiosyncratic part of their ethos. We suggest that in deal communities maintaining prosocial behavior toward out-groups (e.g. retailers, third party payers, etc.) is necessary for collective sustainability. Curbing consumer exploitation of the market ensures the deal collective does not cut the proverbial sheep’s throat.

Our findings provide valuable insight into questionable consumer behaviors, extending and enriching existing understanding (Muncy & Vitell, 1992; Vitell & Muncy, 1992). Some behaviors documented in our investigation, such as taking advantage of price mistakes, can be classified along existing dimensions of the consumer ethics scale such as ‘passively benefiting at the expense of the seller’ (Muncy & Vitell, 1992). Likewise, using expired or counterfeit coupons are examples of ‘deceptive practices’. However, many of the deals described within the collective simply do not fit within existing categorizations of the consumer ethics scale. For instance, stacking deals and coupons from both the retailer and manufacturer in order to make money while purchasing shampoo seems questionable, yet is neither illegal nor immoral. The multiplicity of promotions now available and the sheer crowdsourcing horsepower present in online deal communities make the likelihood of such opportunities emerging ever more likely. It also points to the importance of developing knowledge of when and how consumers react to such deals, which represent a novel form of ambiguous exchange (Belk, 2005).

Managing for Me, Myself, and AI: Why Mythology Hurts AI Investments

EXTENDED ABSTRACT

What consumers believe a given AI solution can or cannot do for them or others in important domains such as work, leisure, individual freedom, and social wellbeing is also shaped by popular cultural tales and science-fiction books and movies rendering humans as being dominated by artificial intelligence technology (so-called AI dystopias) that, by bringing a host of negative meanings into circulation, can significantly harm a firm’s consumer AI investment. For this reason, we argue that explaining the cultural roots and operation of these AI dystopias, as well as developing a set of strategies for successfully combating them, would make a valuable addition to the marketing lexicon as well as to firms seeking to successfully market consumer-facing AI solutions.

However, a seldom discussed risk of consumer AI is its potential to expose companies to a particular type of risk, which we characterize as AI dystopias. Like all consumer experiences, consumer AI experiences are never singular objects or lines of code but complex and evolving social networks comprised of multiple actors, elements, and touchpoints (Lemon and Verhoef 2016). In order for an AI experience to operate effectively, its inherent technological constraints must be reflected in the thoughts and actions of its consumers, who must then adhere to behavioral norms that reinforce the social structures upon which it is built. Amazon’s success with Alexa, for instance, is not only a matter of equipping its devices with new Alexa skills. If Amazon wants consumers to “add Alexa to any room,” it must also equip consumers with a host of new behavioral skills and capabilities around privacy, leisure, work, and society.

AI dystopias are negative tales and myths about a consumer AI experience that are promulgated by experts, bloggers, journalists, authors, and even competitors. Because they can undermine a consumer’s emotional bond with a particular AI solution, they are damaging to a firm’s AI investment. But they can also operate as diagnostic tools. Dystopian technology framings around Amazon Echo’s family of voice-enabled “Alexa” assistants, for instance, have routinely disparaged Alexa as a harmful invader of privacy and perpetuator of socially problematic biases. Similarly, Tinder’s algorithm-enabled dating app has been frequently accused of turning people into sex objects and romantic dates into superficial and often traumatizing experiences. By developing a set of behavioral skills and capabilities for consumers, however, Amazon and Tinder were able to successfully counteract some of these technophobic consumer AI meanings, and their experiences have gained wider marketplace appeal. AI dystopias have also been an issue for many other consumer AI providers including Facebook and Uber.

To explore these issues in greater detail, we draw on research that has examined technology consumption as an emotional identity project - a matter of perceived meaning and cultural mythology than an aggregation of verified evidence (Mick and Fournier 1998; Best and Kellner 2001; Thompson 2004; Kozinets 2007; Giesler 2012). Previous studies investigating “the American relationship with technology” (Kozinets 2007, p. 871; Mick and Fournier 1998), for instance, consistently diagnose an “ambivalent stance” (Thompson 2004, p. 165) toward technologies such as machines, techniques, and processes, alternating between technophilic stories that “present the
current technologies as our salvation” and technophobic narratives that “see the emergent technology as our damnation” (Best and Kellner 2001, p. 155).

When, as this scholarship argues, technology consumption is better understood as an emotional identity project, the marketing success of consumer AI may not merely be a question of a product’s generalized capabilities (Goldfarb 2018). Rather, it may be a function of how marketers can foster a consumer AI experience’s congruence with extant social norms (e.g., Humphreys 2010). AI dystopias will invariably compete with a company’s efforts to emphasize its consumer AI’s positive role in serving (rather than undermining) an identity project and related problems and challenges. We refer to these positive meanings, which express a perceived dominance of humans over AI technology, as AI solution myths.

The goal of our paper is to examine how AI dystopias influence the marketing success of consumer AI and to offer a new set of strategies that managers can use to protect their consumer AI investment. Our paper is divided into two larger sections, each answering one key question around the management of consumer AI. First, we review what key AI dystopias (and solutions myths) are in circulation and what mythological traditions they might stem from. After that, we discuss what strategies managers of AI can use to counteract them.

Quantification, Algorithms and Agency

EXTENDED ABSTRACT

Software interfaces are now integral to an increasing array of consumer goods. With the proliferation of the ‘internet-of-things’ this is only set to increase manifold. Algorithms are the basic building blocks of software and range from simple ‘if-then’ statements to complex arrangements in neural networks and artificial intelligence. Consumer experiences then increasingly include interactions with the algorithms that make up software interfaces. The sociologist Madeleine Akrich argues that “like a film script...objects define a framework for action” (Akrich 1994). User facing algorithms are one of the most explicit forms of such scripts which mediate consumer experiences.

More importantly, when products with algorithms are incorporated into consumer practices, these algorithms mediate the practices themselves. In this research we study how algorithms shape the consumer practices into which they are introduced. Bruno Latour gives the example of an angry person who has an intention to seek vengeance, which he terms their program of action (Latour 1994). If this person finds a loaded gun, then their original program of action is mediated by the program of action of the gun (of accelerating metal). Similarly, in our research, we ask how algorithmic programs of action influence consumers’ programs of action. We study this in the context of consumers using fitness-tracking devices and apps such as Fitbit, Apple Watch and Strava.

Self-tracking is not new. People have long used pen and paper or measuring tapes for self-tracking. So, in what important ways is algorithmically infused self-tracking different? First, the self-tracking with these devices is highly automated. Once started, data is constantly and automatically generated. Second, the output of these devices is highly number focused. With a pen and paper, a person can reflect on their experience in a more holistic manner. With a measuring tape this reflection is brought down to a single number. Now, with algorithmic devices the quantity of numbers is multiplied with a variety of statistics being generated. Lastly, these devices are animated. That is, they ‘speak’ to the user through data visualizations and algorithmic notifications. Whereas previous research has looked at information technology as augmenting the capabilities of the consumer (Jenkins and Denegri-Knott, 2017), we draw attention to the dynamics of and negotiations in such augmentation and foreground the user interactions with algorithms.

Theoretically, we draw on actor-network theory (Latour 2005), practice theory (Schatzki 1996, 2002) and speech act theory (Austin, 1962). In his articulation of practice theory, Theodore Schatzki makes a distinction between dispersed and integrated practices (Schatzki 1996). For instance, in the integrated practice of giving a lecture, the dispersed practices of explaining and questioning play a role. Dispersed practices can be parts of several different integrated practices. Further, Schatzki sees practices as a nexus of doings and sayings organized by understandings, rules and what he calls teleaffective structures (Schatzki 1996, 2002). Teleaffective structures refer to the normative ends and emotions associated with a practice. Lastly, we draw on the concept of performativity (Austin 1962), which in speech act theory refers to the ability of utterances to create facts. That is, words do not just describe the world, they often create things in the world. For instance, when a pastor says, ‘I pronounce you husband and wife’, they create something.

Performativity is at play when algorithms sense, classify and quantify the world and represent them to the user as data visualizations and user notifications. The effect of this algorithmic performativity is to create facts about the world. However, it is important to note that algorithms are created within the affordances of computational constraints, especially that of seeing the world as numbers. While working within these constraints, algorithms introduce new dispersed practices into the consumer’s integrated practices in such a way that it often creates tensions with the original integrated practice. That is, the teleaffective structure of the practice is changed because of the inclusion of the algorithm.

We find the combined effect of quantification and networked sociality orchestrated by algorithms impacts consumer agency in novel and powerful ways. The most common impact is consumers’ acceptance of algorithm anointed metrics as a legitimate way to relate to their practices and themselves. Further, when consumers introduce algorithmic devices into their practices, they pay more attention to those aspects of the practice which are privileged by the algorithm. The algorithm is thus implicated in shaping consumer practices according to its own logics and affordances. In contrast to marketing messages which promote tracking devices as a form of consumer empowerment, we show that algorithmic interactions involve important negotiations of consumer agency with the algorithms ‘program of action’.

Benevolent Surveillance? Enhancing Efficiency and Employee Safety with AI

EXTENDED ABSTRACT

The dominant perspective in research on the quantified self assumes, and sometimes even asserts, that monitoring and measuring of the body and behavior are explicitly part of self-improvement (Lupton 2016): we monitor and measure, so we can improve. The quantified self has been largely characterized as a movement toward self-awareness and self-knowledge. It often treats the choices AI programmers make as to what is monitored and how it is measured as value neutral (Whitson 2013). In sharp contrast, the Foucauldian perspective treats AI surveillance as a tool for corporate and institutional control and shows how the scientization of data strategically strips people of their agency, turning them into data specimens (Abrams 2004). Likely, the reality is somewhere in between agency and control.
Advances in wearable technology, wireless communications, analytic software and mobile content can be integrated powerfully in workplace AI with the potential to revolutionize contemporary workplaces. Workplace AI claims to transform health and safety practices by making predictive, adaptable and personal behavioral recommendations (Brougham and Haar 2018). AI technology makes it possible to measure and record all the physical behavior of an individual worker over a short period (a day) or a longer period (a week, month or year), link them to efficiency metrics like throughput, output and project advancement, and observe patterns.

Workplace AI benefits the organization in the form of greater efficiency, lower absenteeism due to injury, lower insurance costs and worker compensation claims (Brynjolfsson, Rock, and Syverson 2018). Perhaps more pointedly, workplace AI can locate patterns of employee efficiency (what behaviors lead to metric attainment) which can lead to codifying specific practice regimes that are most likely to yield success and surveilling employees to ensure they are following the successful regimes. Workplace AI benefits individual workers in terms of health and safety, but at the expense considerable privacy and task autonomy. Surveilled employees have less agency in their job performance. Unions are somewhat ambiguous about the use of AI technology in the workplace. On the one hand they value the health and safety benefits it affords workers, but on the other they are concerned about invasions of privacy by means of surveillance, the loss of agency due to potentially aggressive nudging of employees into specific codified behavior regimes and that greater productivity gains are not necessarily rewarded by compensation.

We investigate the nexus of consumer AI, created and sold in the domestic sphere for self-enhancement, and AI developed for corporate workforce control. Our data consist of worker data streams and interviews. The data streams are culled from an open-innovation platform that links sensing applications that provide real-time visibility into a workforce to identify, mitigate, and manage risks, ostensibly to prevent workplace injuries. The platform pairs sensors on specific industrial motion tracking wearable sensors with cloud-based analytic software to detect and provide early warning of heightened injury risk. Sometimes using the same sensors, the platform co-opts consumer AI promising enhanced safety and efficiency, turning personal, domestic devices assumed to be created for self-enhancement, and AI developed for corporate workforce control. Our data consist of worker data streams and interviews conducted with supervisors and line employees of client firms actively using the platform in their daily operations.

The data the platform offers clients are aggregated (a complete overview of the movements and physical behavior of the workforce), aggregated into divisions, aggregated into functions, aggregated into use patterns (highly successful employees or employees struggling to meet metrics) and individual (a single employee). It is possible to observe movement in space, posture, lifting and carrying behavior, and where necessary advise that worker to change their posture, walking and movement patterns etc., both ostensibly to increase efficiency and to safeguard the physical wellbeing of the individual worker. The current clients of the company include firms in the airline, retail, and manufacturing sectors. The workflow data streams that we will present will be at an aggregate level for an anonymous client company and its labor force, and illustrations of individual patterns will also be anonymous examples. Likewise, interview data will be redacted for client and employee anonymity.

Our preliminary findings suggest that AI does enhance health and safety practices but over time, can decrease employee morale as they perceive their professional agency being eroded. Interestingly, employees utilizing entirely industrial AI devices and apps experienced less morale decline than those where workplace AI co-opted consumer AI devices and apps.

SESSION OVERVIEW
Choosing and consuming are activities that provide individuals with opportunities to develop and enact their preferences, express who they are (or would like to be), and experience a sense of self-determination in their lives. In contrast, modern marketing, based on economic theory and enabled by technology, primarily aims at efficiency by addressing consumers on the basis of predetermined classifications, using segmentation and product differentiation. Borrowing from Karl Marx, the session asks when marketing may, in fact, alienate consumers. Collectively, the four papers in this session ask how current marketing practices geared to enhance economic efficiency—from standardized production methods, identity appeals/segmentation, the digitization of products and services, to algorithmic microtargeting—can frustrate, or serve, consumers’ fundamental human needs to autonomously express, choose, and adapt their identity and preferences on their own terms, not as predetermined by marketing techniques.

Three papers examine consumer reactions to marketers’ attempts to enhance efficiency (by microtargeting, segmentation, and product differentiation) that insufficiently address consumers’ needs to manage their own preferences and identity. The fourth shows how marketers can enable transactions that counter alienation and enhance opportunities for identity expression.

Schrift et al. address how microtargeting based on machine learning and artificial intelligence may undermine consumer perceptions of free will and autonomy. Drawing consumers’ attention to the predictability of their choices threatens their sense of autonomy and prompts them to restore it by choosing non-predicted and therefore non-preferred choice options, a paradoxical effect of microtargeting efforts to offer consumers their most preferred choice options.

Kim at al. demonstrate that identity appeals, a standard segmentation and targeting method, can backfire, alienating the very individuals they aim to attract. That is because consumers are loath to being reduced to a single identity or aspect of their individuality. The authors explore boundary conditions of this phenomenon, such as when the targeted identity evokes negatively laden stereotypes or membership in marginalized groups.

Cito et al. show how the dematerialization of products (e.g., downloading and streaming versus tangible books, CDs, or DVDs), a modern product differentiation method based on digitization, limits consumers’ ability to pursue identity-relevant goals through their consumption activities, in contrast to material consumption goods, which establish a stronger and more physical link with the identity they represent.

Finally, Kaiser et al. take a historically inspired perspective on alienation, pointing to an important linkage between production and consumption at the heart of the value creation process in marketing. Individuals’ motivation and performance in production tasks depend on how much they can identify the output of their labor as their own and can experience agency in their work. Even simple acts of personalizing products can enhance both motivation and performance.

Given the growing societal and political scrutiny of the digitalization of marketing, the session will appeal to a broad cross-section of researchers interested in how marketing and technology are affecting fundamental aspects of consumers’ selves and identity. While all four papers address aspects of alienation, each provides distinct conceptual and substantive contributions, drawing on social psychology, sociology, economics, and philosophy.

The Dark Side of Microtargeting: Predicting Consumers’ Preferences Threatens Their Sense of Free Will

EXTENDED ABSTRACT
The belief in free will and its associated sense of autonomy is a fundamental aspect of intrinsic motivation (e.g., Deci, Koestner, and Ryan 1999; Ryan and Deci 2000). It is directly linked with, and asserted, by individuals’ freedom to make choices (Deci, Koestner, and Ryan 1999; Kim et al. 2015). Recent developments in machine learning and artificial intelligence allow marketers to microtarget consumers and predict their choices more accurately and efficiently than ever before. Modern recommendations systems use consumers’ demographic characteristics and track their past choices, decision processes and, presumably, even their psychographic characteristics to tailor offers to consumers (Matz et al. 2017; Kosinski et al. 2014, Zwebner and Schrift working paper). Might such attempts to influence and predict individual behavior threaten consumers’ sense of free will? If so, why and how will consumers react to such practices?

Philosophers who question the existence of free typically propose two alternative governing principles of nature, which preclude free will, causal determinism and its opposite, indeterminate randomness (Kane 2005). In contrast, we propose and find that consumers wish to experience and perceive their choices as neither random nor deterministic. Specifically, we hypothesize that framing consumers’ choices as consistent with their preferences primes consumers to consider their choices are non-random. Not having to attribute their choices to randomness allows consumers to maintain an unperturbed belief in free will. They can view themselves as the causal agents of their choices. In contrast, framing consumers’ choices as predictable suggests to consumers that their choices may be predetermined and outside of their control, undermining their belief in free will. Note
that from a normative utility perspective, consistent preferences and predictable preferences are indistinguishable and imply one other.

In Study 1 (N=401) participants freely wrote about what they perceive to be the meaning of being “predictable”, “unpredictable”, “consistent”, or “inconsistent” (manipulated between-subjects). Using Natural Language Processing, we text-analyzed participants’ responses. A valence analysis revealed that being consistent produced higher positive valence scores compared to being predictable, and that being unpredictable yielded fewer negative thoughts compared to being inconsistent. The 2 (predictable vs. consistent) x 2 (being vs. not being) interaction was significant. These findings provide initial evidence supporting our claim. Specifically, being predictable implies having a deterministic preference structure. However, being consistent merely implies a non-random preference structure. Thus, while the former threatens perceptions of free will, the latter reinforces it. Consistently, negating these terms (i.e., using the terms “inconsistent” and “unpredictable”) reverses the meaning implied and produced opposite patterns.

In Study 2 (N=153) participants first completed a self-explained conjoint analysis about vacation preferences. After a filler task, participants were asked to choose their most preferred vacation package from three choice sets containing five options each. Prior to choosing, participants assigned to the predictability condition were told that one could predict their impending choices based on the preferences they indicated in the first stage of the study. Participants assigned to the consistency condition were told that one could see how consistent their choices were with their previously stated preferences. Participants’ choices in the predictability condition deviated more from their original preferences compared to choices made by participants in the consistency condition.

One could argue that the effect is mainly driven by participants in the consistency condition which are motivated to choose more carefully in order to exhibit consistent behavior in the lab. However, Study 3 (N=167) which included a control condition (in which neither predictability nor consistency were highlighted) alleviated this concern. Specifically, results confirmed that participants’ choices in the predictability condition deviated from their originally stated preferences significantly more compared to those in the consistency and control conditions. This study replicated the pattern observed in Study 2 and showed that the effect is driven by the deviation in the predictability condition.

In sum, we find the notion that one’s preferences may be predicted is concerning to consumers, threatens their sense of free will, and leads them to deviate from their preferences in order to reassert their sense of free will. However, such effects attenuate when predictability is framed as consistency, because such a frame does not trigger a deterministic view with regards to one’s preferences. Our findings suggest how microtargeting activities might be framed to be more, or less, palatable to consumers.

Calculators for Women: When Identity Appeals Provoke Backlash

EXTENDED ABSTRACT

From Chick Beer to Mangria, hand tools “for Women” to dryer sheets “for Men”, examples of identity-based labeling—or “identity appeals”—abound. Oftentimes these appeals serve a practical function: increasing attraction from members of the appealed-to population. Indeed, previous research on labeling theory shows that invoking an identity can motivate individuals to conform to characteristics of that identity (Kraut, 1973; Schur, 1971).

In practice, however, the effectiveness of identity appeals has proven more complex. For instance, uproar ensued when BIC released the “Pens for Her” series; Target Inc. faced consumer ire after one store labeled an aisle “Building Sets” and another “Girls’ Building Sets”. In 2016, Hillary Clinton’s supporters appealed to women to support the first female presidential candidate specifically because of their shared gender, but instead provoked backlash from many voters.

Why did these identity appeals go awry? We investigate when and why identity appeals backfire, alienating the very individuals they aim to attract. We posit that identity appeals can induce categorization threat (i.e., being categorized unwillingly into a single identity)—and in turn, backfire—when a) the evoked identity is that of a typically marginalized group and b) the appeal evokes a stereotype about that identity.

Study 1 tested whether identity appeals will backfire when the two categorization threat-inducing factors are present. We distributed (unofficial) campaign materials for Hillary Clinton the summer before the 2016 presidential election. We gave female participants (N=199) the choice between a lower-value sticker or a higher-value button and varied whether the button had an identity appeal (“Candidate for Women”). Note, the identity appeal evoked a stereotype (i.e., Hillary Clinton was stereotyped as a candidate for women during the 2016 presidential election) about a marginalized identity (i.e., women are more marginalized than men). Indeed, most participants in the no appeal condition chose the button over the lower-value sticker (60.8%)—significantly different from chance, p=.04 (not surprising given that the button was more expensive and higher quality). However, when the button featured a slogan using an identity appeal, “Hillary, the Candidate for Women,” marginally fewer participants chose the button over the sticker (47.5%), p=.06, forgoing the objectively better-quality product.

Study 2 (N=321) was 2(participant gender: male, female) by 2(偈ibility appeal: yes, no) between-subjects. All participants chose between two calculators to complete math problems. Participants in the no identity appeal condition saw green and purple calculators. Those in the identity appeal condition also saw the same options, except the purple calculator was labeled as “for Men” or “for Women,” depending on their gender. We predicted that women would avoid the purple calculator when the “for Women” appeal was affixed, since both factors would be present: the identity appeal evoked a stereotype (“Most women like purple”) about a marginalized identity (i.e., women are more marginalized than men). There was a significant interaction between participant gender and identity appeal, p<.001. Fewer female participants chose the purple calculator in the identity appeal condition (24.1%) than those in the no appeal condition (51.1%), p<.001. In contrast, if anything, men were more likely to choose the purple calculator with an appeal to their male identity (47.3%) than without one (31.9%), p=.06.

Study 3 was a 2(participant gender: male, female) by 2(stereotype evocation: yes, no) between-subjects design, and focused on the first factor, testing whether—for identity appeals to backfire—they must pertain to a marginalized identity. Participants (N=600) were presented with two articles (about morals and emotions), and encountered an identity-relevant appeal: female and male participants saw the emotions article labeled for “Women” and “Men” respectively. To manipulate stereotype evocation, half of participants were told that their gender was typically viewed as bad at managing emotions (pretested as credible to both genders). We tested whether—for an identity appeal to backfire—the evoked stereotype must be linked to a marginalized identity by comparing female (a marginalized group) and male (a non-marginalized group) responses. Indeed, there was a
significant interaction, p=.02. Female participants in the stereotype evocation condition were significantly less likely to choose the article on emotions than those in the stereotype non-evocation condition, p=.01. Preference for the article on emotions amongst male participants did not differ whether the emotions stereotype was evoked or not evoked, p=.41. Perceptions of categorization threat also followed the same pattern; differences in article preferences between the stereotype evocation and non-evocation conditions were mediated by categorization threat and moderated by participant gender.

Study 4 provided converging evidence for the first factor. Female participants (N=189) chose between two calculators (green, purple). Those in the identity appeal condition saw the purple calculator with an identity appeal while those in the no appeal condition did not. We also included a trait measure of public regard: people’s perceptions of how well-regarded their gender is by others. There was a significant interaction between identity appeal and public regard, p=.02: stereotype-evoking identity appeals backfired only among women who chronically feel that their gender is being marginalized by others.

Study 5 focused on the second factor by manipulating whether the identity appeal evoked a stereotype. Female participants (N=204) chose between two pens (purple, green). Informed by our pretest demonstrating that purple evokes a stereotype (“Most women like purple”) while green does not, we varied which color the identity appeal accompanied—either a “purple pen for women” or a “green pen for women.” A third, baseline condition excluded identity appeals altogether. At baseline (no appeal condition), 65.6% chose a purple pen; however, far fewer participants chose the purple pen when it bore the label “for Women” (45.8%), p=.02. Importantly, by contrast, the non-stereotype-evoking appeal (i.e., ascribing “for Women” to the green pen) did not backfire: participants were just as likely to choose the green pen when it was paired with an identity appeal (23.5%) relative to when no appeal was made (34.4%), p=.17.

Our work suggests that a mere label can produce unintended downstream consequences: while identity appeals to non-marginalized, non-stereotyped groups can have a neutral or even beneficial effect, identity appeals to other groups have a negative and even backlash effect.

The Dematerialization of Consumption

EXTENDED ABSTRACT

The world is shifting towards the digital realm at an ever-growing pace. Only a few years ago, consumers had to buy physical books or DVDs in brick-and-mortar stores. However, these products are dematerializing: they are now mostly invisible and intangible. Dematerialization brings many consumption benefits. For example, with an e-book you can easily resize the font or search within the text. However, despite the indisputable benefits of dematerialization, we propose that consumers may at times prefer material goods over their immaterial counterparts. We also propose that this is the case for consumers who want to reinforce their identity through consumption due to the greater ability of material products to remind their owners' self-concept (i.e., self-verifying ability). In particular, material products have higher self-verifying ability because, compared to their immaterial counterparts, they establish a stronger and more physical link with the identity they represent. According to Pierce’s semiotics framework, products can act as “indices”, signs with a physical, real connection with what they represent.

We tested our hypothesis that consumers prefer material products under identity-based consumption in 7 studies. The goal of studies 1a-1d is to demonstrate preference for materiality among identity-driven consumers. We tested our key prediction – that strength of identification predicts preference for material products (vs. their immaterial counterparts) – in four studies with different product categories and different measures of strength of identification.

In study 1a (802 participants recruited on MTurk), we tested if consumers’ preference for materiality of identity-related products increases with strength of identification. We measured participants’ strength of identification as a gamer (self-report), manipulated the identity relevance of a book (gaming vs. cooking book), and asked participants to choose between a material and an immaterial version of the book. Results reveal that consumers’ strength of identification increases the preference for materiality of the identity-relevant products: Strong identifiers preferred the material version of the identity-related product, but the immaterial version of the identity-unrelated product. In study 1b (596 participants recruited on Prolific), we tested our key prediction using a behavioral proxy for strength of identification. Specifically, we used the number of hours spent weekly playing videogames (as reported by participants on a separate survey conducted by Prolific) as a proxy for how much participants identified themselves with the identity of gamer. Results confirm the findings of study 1a. In study 1c (514 students from a Dutch university) we provided further evidence on the link between identification and preference for materiality. Participants were asked to imagine being devoted fans of one of two directors (our manipulation). Then we showed participants a movie directed by one of these two directors and measured their preference for obtaining a material (vs. immaterial) copy of the movie. Thus, the movie was either identity-related or unrelated, depending on the match between the manipulated identity and movie shown. We found a preference for materiality only for identity-related movie and not for the other one. In study 1d (401 Prolific participants), we replicated our results with yet a different identity manipulation, which asked participants to name a singer whose work they identified with (vs. that they neither liked nor disliked). In addition, we manipulated the presence of an extra material product (a factor we called “rematerialization”). Participants in the “rematerialization” conditions were told that together with the music album (regardless of whether they chose the physical or the digital version), they would receive a tangible artefact (a physical book about the production of the new album). Participants in the “no-rematerialization” conditions made a choice between the physical and the digital version without receiving any other extra product. The effect replicates even when the target product is accompanied by a separate material good, further demonstrating the robustness of the effect of identity on preference for materiality.

In study 2 we provided first evidence for our proposed process: self-verification. As demonstrated in studies 1a-1d, identity-driven consumers tend to prefer material products. We argue that this occurs because material products have higher self-verifying ability: When consumers buy a product related to their identity (i.e. a book from an author they identify with), they prefer the material version (i.e. a physical copy of the book) instead of the immaterial one (i.e., an e-book) because the material product (the book) is a better reminder of who they are. In study 2 (202 Prolific participants), we demonstrated that material products have higher self-verifying ability than their immaterial counterparts. We asked participants to rate a material vs. an immaterial identity-related product on three different benefits: utilitarian, hedonic and self-verification. We found that a material product allows greater self-verification, higher hedonic value, and lower utilitarian value than its immaterial counterpart.

In study 3 (404 MTurk participants) we tested the self-verification account using an inference method. We asked participants to infer someone else’s identity looking at her physical vs. immate-
rrial possessions. We found that the books on a shelf are perceived as better clues into one’s identity than e-books in a kindle library.

In study 4 (803 MTurk participants) we further test our process by manipulating the extent to which a product allows self-verification. Thus, we asked participants to imagine buying a book vs. borrowing it (i.e., buying a product is more self-verifying than borrowing it). We found that when products have higher self-verifying ability (i.e., products that could be bought), consumers prefer the physical version of the identity-related products. When products have lower self-verifying ability (i.e., products that could only be borrowed), the preference for materiality disappears.

In sum, the studies highlight that the transition from material to digital products is likely to have a dark side for consumers, who find it harder to fulfill identity goals through consumption in the absence of material products.

The Signature Effect: How Personizing the Fruits of One’s Labor Increases Work Motivation and Performance

EXTENDED ABSTRACT

If you open the hood of a Mercedes-Benz AMG you can sense their “One Man – One Engine” philosophy by inspecting the signature of the engineer who was responsible for the assembly. Similarly, Known Supply garments include a tag with the laborer’s signature on it, and Lush Cosmetics even print stickers with a picture and name of the creator along with the date of production on their products. Other companies like the snack manufacturer Burts Chips, for example, go the creator along with the date of production on their products. Other Known Supply garments include a tag with the laborer’s signature on it, and Lush Cosmetics even print stickers with a picture and name of the creator along with the date of production on their products. Other companies like the snack manufacturer Burts Chips, for example, go even further and feature rich personal information on their producers on the products’ packaging. These examples highlight that marketers seem to have (re-)discovered the value of making the individual producer and the fruits of their labor, the product, more personal by revealing the respective individual producer’s identity at the point of purchase.

While customers have always had this type of informational detail when interacting with individual craftsmen (think of the tailor making your suit) or farmers (think of the farmer selling potatoes at the local market), recent technological advancements have facilitated such personizing strategies in mass production settings, making the tracing back to the origin of a given product’s production process feasible at scale. But what are the effects of this trend? Recent research suggests that making the individual producer more personal produce favorable effects among consumers; i.e., they prefer to buy products from firms where they know and can thus better connect to the individual producer (Fuchs et al. 2018).

In this research, we take a different perspective: Instead of looking at what such personizing treatments do with consumers, we investigate how making the individual producer more personal affects the producer. Specifically, we ask whether and why personizing the fruits of one’s labor affects work performance. We define our focal term personizing as providing personal information about the producer of a given product on the product or the product’s packaging. If we think of individual producers as brands, this is not much unlike of what the original meaning of the word branding intended to convey (think of hot branding livestock to identify the owner).

We theorize that branding a product with one’s identity once finished increases work motivation through feelings of de-objectification. Objectification denotes perceiving or treating other people as objects. When a person is objectified, she is treated as a means to one’s ends and deprived of her essential human capacities such as agency, autonomy, and self-determination (Frederickson and Roberts 1997; Nussbaum 1995). For our context, we use the term de-objectification to describe a producer’s feelings of being appreciated and valued as a unique human being rather than feeling like an interchangeable worker. By having been granted the possibility to visibly brand the fruits of one’s labor with one’s identity, ceteris paribus, we argue that one and the same task becomes more personal, less objectified, and hence more meaningful. This process, in turn, should increase work motivation and performance.

Four studies in the lab and in the field demonstrate the existence of this effect. Alternative explanations including mere accountability concerns or self-identity primes are ruled out. In study 1, museum visitors of an exhibition about artisanal handicraft at a renowned museum of Applied Arts were invited to decorate a pre-cut Christmas angels. Participants (n = 59) were truthfully told that their angels would be prominently exhibited in the museum upon completion of the study. The study was a two-cell between-subjects design. The focal manipulation was whether participants put their name or signature on the angel or not. The quality of the decorated angels, as judged by a panel of three expert raters, served as dependent variable. Findings confirmed our prediction: When museum visitors branded the product with their name, quality was significantly higher compared to the control condition (non-signed angels).

Study 2 (n = 230) and study 3 (n = 152) replicate and extent this effect in the field. Amazon’s micro-labor platform Mechanical Turk serves as field setting. Here, we can more convincingly talk about work, and not leisure (in the museum study, participants voluntarily completed a drawing task in their leisure). Workers were asked to produce three drawings an alien (i.e., a creative task, study 2) or five drawings of a sheep (i.e., a mundane task, study 3), respectively. The manipulation was whether participants signed their drawings or not. Findings show that our basic effect extends to a setting where higher quality is presumably related to taking higher risks (drawing an alien is used in creativity tests and outcomes of such highly creative tasks can either be seen as great or awkward) and also to mundane, more repetitive task (in study 3, participants were asked to draw five sheep; we did not observe any treatment x replicate interaction).

Finally, study 4 (n = 121, undergraduate students) confirms our proposed de-objectification account. The study was a two group within-subjects experiment. Participants were asked to produce two snow globes, one of them signed, the other one not (participants were asked to put an ID on the globe instead; the order of the task was counterbalanced). Findings show that participants feel less objectified regarding the signed and personized globe compared to the non-signed globe. Participants also reported that the signed globe was more enjoyable to work on. Finally, independent judges rated the quality of the signed and personized snow globes more favorably. Feelings of de-objectification mediate the signature effect on product quality.

Taken together, four studies highlight that certain marketing strategies aimed at producing favorable effects among consumers can also effect changes in the organization itself. Making the individual producer and the fruits of his or her labor, the product, more personal at the point-of-purchase does not only affect consumer preferences (Fuchs et al. 2018) but, as demonstrated in the present research, also increase work motivation of the personized producers. More generally, our research contributes to the literature on alienation of consumers and producers and interventions about how to make work and consumption more meaningful (Campbell 2005; Grant et al. 2007).

The Machine Age of Consumer Research: How Robot-Based Expression Modalities Alter Perception and Choice

Chair: Christian Hildebrand, University of St. Gallen, Switzerland

SESSION OVERVIEW

Recent advances in artificial intelligence and natural language processing are giving rise to technology that can appear progressively more human-like, both physically and emotionally, bringing us closer to Turing’s (1950) definition of machine intelligence as the inability to discern an interaction with the machine from one with another human being. From next-generation digital voice assistants (such as Amazon Alexa or Siri) to realistic sounding and looking humanoid robots employed as news anchors or hotel staff (Forbes, 2019), human-like technologies permeate through the fabric of consumers’ everyday lives. However, whether, how, and to which extent these novel expression modalities alter fundamental perceptions of humanness, consumer choice, and the brands providing such technologies remains unclear.

The goal of this special session is to shed light on a burgeoning field of research on how consumers perceive humanness in non-human agents and the psychological consequences of consumers’ engagement with such technologies. The session will be comprised of four papers that explore two central research streams:

1. Mind perception in human-machine interaction
2. Anthropomorphic agents in consumer-firm interactions

The first two papers in this session explore the first stream. Schroeder and Epley explore what cues make people mistake a human for a machine, or a machine for a human. They find that human-like voices are particularly important for conveying the humanness of a communicator, in comparison to other (e.g. visual) cues. Next, Castelo, Schmitt, and Sarvary explore the consequences of robots possessing a human-like mind based on expressions of autonomy and emotional ability. They find that increasing the belief that social robots can have minds increases empathy for – and valuation of – robots.

The third and fourth papers explore the second research stream, focusing on the downstream consequences of anthropomorphized technology. Bergner, Hildebrand, and Häubl demonstrate the effects of conversational interfaces on brand perceptions and purchase decisions. They show that incorporating such interfaces into the shopping process promotes more intimate consumer-brand relationships and increases consumers’ inclination to choose premium offers compared to traditional interfaces. Finally, the session concludes with work by Hadi, Crolic, Thomaz and Stephen, who investigate the interplay between chatbot anthropomorphism and anger in a customer-service context. The authors find that cues of humanness can severely backfire such that angry consumers are less satisfied when addressed by anthropomorphic (versus non-anthropomorphic) chatbots, and this effect even extends to company evaluations and purchase intentions.

This special session contributes to the conference by showcasing research that addresses fundamental questions on how technology-mediated expression modalities can alter perceptions of humanness and the type of choices that consumer make in response to using these technologies. The papers in this session span multiple disciplines from the psychology of mind to computer science and the communication sciences. We hope that this session helps to inspire more scholarly work in this fast-growing field of interdisciplinary academic research.

Mistaking Minds and Machines: How Speech Affects Dehumanization and Anthropomorphism

EXTENDED ABSTRACT

Alan Turing (1950) created a famous benchmark for determining whether a computer can “think.” When it can convince a majority of people that they are interacting with another person instead of a machine (i.e., the Turing test). One thing that makes the Turing Test particularly difficult is that it occurs in the written medium, a dehumanizing space in which little is known about the communicator other than the words they express. Presumably, adding humanizing cues to the written medium may make people more likely to infer that the communicator is human—but which cues in language most clearly convey humanness?

This question is critically important because the modern world has become a living Turing Test, where people must constantly infer whether they are interacting with a human or machine. For example, customer service agents, social media users, and even secretaries are often automated chatbots instead of living humans. Moreover, newly developed artificial intelligence such as “deepfake” and Google’s Duplex voice assistant now have convincingly human-like voices. Given this trajectory, future machines are likely to have many humanlike characteristics (voice, faces, and so on), leading to increasing difficulty in assessing whether one’s interaction partner is a human or machine.

Prior experiments have tested how language cues humanize a communicator by manipulating the communication medium by which a communicator is observed, and measuring resulting perceptions of the communicator’s mental capacities (Hall & Schmid Mast, 2007; Kruger, Epley, Parker, & Ng, 2005; Schroeder & Epley, 2015; Schroeder, Kardas, & Epley, 2017). Results indicate that communicators are perceived as having stronger mental capacity (and thereby humanized) when their message is heard (via audio-clip) or seen (via videotape) versus when read (via text). Interestingly, seeing a communicator in addition to hearing him or her does not meaningfully
influence assessments. This suggests that the human voice may be particularly important for humanizing a communicator. Supporting this idea, adding a humanlike voice to computerized agents increases anthropomorphism (Nass & Brave, 2005; Takayama & Nass, 2008; Waytz, Heafner, & Epley, 2014). Moreover, observers can infer a speaker’s mental states even via short vocal bursts (which lack semantic content; McAleer, Todorov, & Belin, 2014; Scherer, Banse, & Wallbot, 2001; Weisbuch, Pauker, & Ambady, 2009). These findings led us to predict that the presence of a humanlike voice may particularly enhance perceptions that an agent is human.

The current paper presents four experiments testing whether adding (or removing) human voice from an agent influences perceptions of whether it is a machine or person—and compares the effect of voice to other cues (e.g., face). In Experiment 1, 647 observers evaluated one of 40 possible videos of communicators talking about positive or negative emotional experiences and subsequently guessed whether the statement had been created by a “human or computer.” They observed the statement in one of four experimental conditions: audiovisual (watching a communicator’s video), audio (listening to the video on black screen), subtitled-video (sound removed), or text (reading the subtitles only). As expected, observers who read the speeches were less likely to believe it was created by a human (text condition: M=53.6%, SD=50.0%) than observers who listened to them (M=80.8%, SD=39.5%), t(627)=5.29, p<.01, d=0.42, but adding visual cues to either condition (text or audio) did not meaningfully increase perceived humanness (subtitled-video condition: M=60.7%, SD=49.0%; audiovisual condition: M=71.6%, SD=45.2%).

Experiment 2 next tested the inverse question by using computer-generated statements (from an online “postmodernism generator”) that were read aloud by ten human communicators. Observers were assigned to one of the same four experimental conditions (audiovisual, audio, subtitled-video, or text) and made the same estimate. Replicating Experiment 1, observers who listened to the speeches were more likely to guess the script was created by a human (M=60.0%, SD=49.4%) than did those who read identical speeches (M=32.3%, SD=47.1%), t(239)=3.14, p<.01, d=0.41. Adding visual cues did not significantly increase perceived humanness (subtitled-video: M=39.3%, SD=49.3%; audiovisual: M=40.0%, SD=49.4%); in fact, it unexpectedly decreased it in the audiovisual condition.

Experiment 3 compared whether humanness perceptions change based on the type of text presented—whether a written statement or transcript. 18 communicators both spoke and write about their job credentials. 273 observers either read the written statements, transcribed-speeches, or listened to spoken statements. Observers who listened to the statements were more likely to believe it was created by a human (M=79.1%, SD=40.9%) than did those who read them transcribed (M=55.9%, SD=49.9%), t(270)=3.34, p<.01, d=0.41, or read the written statements (M=59.6%, SD=49.3%), t(270)=2.74, p=.01, d=0.33.

Finally, Experiment 4 manipulated vocal characteristics by asking communicators to speak aloud written statements either “mindfully” (e.g., “try to convey the communicators’ thoughts and feelings in your voice”) or “mindlessly” (e.g., “read the words with little feeling”). Observers (n=300) either listened to the mindful voices, listened to the mindless voices, or read the written statements. More observers guessed that the essay was created by a human when they listened to the mindless voices (M=65.0%, SE=4.6%) than when they read the text (M=47.2%, SE=6.5%), χ²(1,180)=5.55, p=.02, ϕ=.18, or listened to mindless voices (M=50.3%, SE=4.6%), χ²(1,240)=5.52, p=.02, ϕ=.15. The text and mindless voice conditions did not differ from each other, χ²(1,180)=.018, p>.10. An analysis of the paralinguistic cues in the mindful versus mindless voices indicated that variance in communicators’ pitch (i.e., their intonation) mediated the voice manipulation on assessments of humanness.

These experiments indicate that humanlike voices are particularly important for conveying the humanness of a communicator. Adding a humanlike voice to computer-generated text increased the tendency to infer that it was actually created by a real person, whereas removing a voice from human-generated speech increased the tendency to presume the content was actually created by a computer. Experiment 4 further suggests a reason why voice is humanizing—variance in the paralinguistic cues in a voice such as intonation may convey an active, human-like mind to an observer. This research contributes to understanding how people perceive humanness in ambiguous agents, with implications for how to design technology to enhance humanness.

**Robot or Human? How Bodies and Minds Shape Consumer Reactions to Human-Like Robots**

**EXTENDED ABSTRACT**

Social robots – intelligent, physically embodied machines that can sense and manipulate their environment, perform tasks autonomously, and engage in social interactions – are becoming increasingly prevalent in many domains of consumer behavior (Simon, 2018). Consumers can purchase social robots that perform chores, engage and monitor young and elderly people, and act as companions and assistants (Gibbs, 2016). Outside the home, social robots are being used in many contexts including retail stores, restaurants, hotels, and hospitals (Dass, 2017; Nguyen, 2016). Some of these robots are extremely human-like in their physical appearance, which consumers often find unsettling and creepy (Wang, Lilienfeld, and Rochat, 2015). These negative affective reactions limit the usefulness of social robots and their ability to provide value to consumers and firms.

We propose that increasing the perception that robots with human-like physical appearances also have human-like minds will make them seem more useful and make consumers more comfortable with them, ultimately increasing their value to consumers and firms. This prediction is based on the ideas that (1) having a mind makes robots capable of having empathy for humans, which facilitates social interactions and therefore help social robots achieve their intended purpose, and (2) having a mind is congruent with a human-like appearance, and such congruence increases positive affect.

In Study 1, 100 MTurk participants watched a video arguing either that robots could or could not have human-like minds, by describing the philosophical positions of physicalism or dualism respectively. Those who watched the video arguing that robots could have minds agreed that robots could have more a human-like mind (M = 6.3 vs. M = 1.8, p < .001), evaluated companies employing robots more positively (M = 4.9 vs. M = 4.1, p = .027), and were more likely to donate to a charity promoting the development of human-like robots (65% donated vs. 44%, p = .074). These results suggest that perceiving robots as having the capacity for a human-like mind increases consumers’ valuation of robots.

Minds are usually perceived along two dimensions: agency (or autonomy) and emotional experience (Waytz et al., 2010) however, always ascribe minds to other people, and sometimes ascribe minds to non-people (e.g. God, gadgets. Study 2 therefore manipulated perceptions of these capacities in robots in a 2 x 2 design. 282 MTurk participants were shown a highly human-like robot and were informed that these kinds of robots could either (1) experience emotions like humans do but not make autonomous decisions; (2) make autonomous decisions like humans do but not experience emotions;
(3) have both capacities, or; (4) have neither capacity. As a measure of usefulness, we asked how useful and competent this kind of robot seemed. As a measure of comfort, we asked participants how comfortable they would be interacting with this kind of robot.

2x2 ANOVA revealed that the manipulations were effective. The robot seemed more useful in each of the three mind conditions than in the no mind condition. Participants were least comfortable with mindless robots, non-significantly more comfortable with robots having either autonomy or emotion alone, and significantly more comfortable with robots having a complete mind. Having both dimensions of mind therefore seems important for increasing both the perceived usefulness and consumers’ comfort with human-like robots.

In Study 3, we tested whether the effects of mind perception differ depending on how human-like the robot looks and whether perceived empathy can explain these effects. 300 MTurk participants were assigned to a 2 (mind vs. no mind) x 2 (low vs. high human-likeness) design. Mind perception was manipulated using the videos from Study 1 and explaining that mind refers to autonomy and emotion specifically. We again measured comfort with and perceived usefulness of the robot, as well as participants’ willingness to shop in a store where the robot is employed. Finally, to measure empathy, we asked participants ‘if they believed that robots could understand what they are thinking and whether robots would feel sympathy for them if they were suffering.

Mind perception and human-likeness interacted in shaping comfort ($F(1,292) = 9.29, p = .002$). Having a mind decreased comfort with the low human-likeness robot ($M_{mind}=5.28, M_{no\_mind}=6.62, p = .002$) but directionally increased comfort with the high human-likeness robot ($M_{mind}=4.38, M_{no\_mind}=3.86, p = .222$). This supports the idea that congruence between physical and mental human-likeness can increase comfort with robots. Usefulness was impacted only by mind perception ($F(1,292) = 11.60, p < .001$). Both robots seemed significantly more useful when they had a mind. Usefulness also had a stronger effect on willingness to shop with the robot ($β = .56, p < .001$) than comfort did ($β = .31, p < .001$).

Mind perception increased both the robots’ perceived ability to take a human’s perspective ($F(1,295) = 18.92, p < .001$) and to have sympathy for humans ($F(1,295) = 32.70, p < .001$). Neither human-likeness nor the interaction affected either form of empathy ($F’s < 2.44, p’s > .104$). The effect of mind perception on usefulness was mediated by the robots’ perceived empathy ($β = .62, 95% CI = [.37, .92]$).

Robots are in fact acquiring increasing levels of autonomy and emotional abilities (Beer, Fisk, and Rogers 2014; Picard 2011). While this acquisition of a human-like “mind” may succeed in making robots objectively more useful, it may also make consumers uncomfortable if having such abilities is not congruent with the robot’s physical appearance. The creators and marketers of social robots should therefore consider how both physical and mental human-likeness together contribute to the value that such robots can provide.

Conversational Interfaces as Persuasion Instruments: Implications for Consumer Choice and Brand Perceptions

EXTENDED ABSTRACT

Advances in natural language processing and the adoption of conversational interfaces gradually transform how consumers interact with firms (BI Intelligence 2016; Dale 2016; Hirschberg and Manning 2015). The use of messenger systems as a new interaction paradigm between human consumers and intelligent bots has been declared as the “next operating system in commerce” (Suri, Elia, and van Hillegersberg 2017; The Economist 2016) and is changing how humans search, shop, and express their preferences (Feldman, Goldenberg, and Netzer 2010; Tang and Guo 2013).

Research on the impact of these novel forms of conversational interaction modalities on consumers is both scarce and predominantly concerned with design and technology-related issues rather than the consequences for consumer behavior. Specifically, the majority of prior work examined either factors related to optimizing system design features (Landis 2014; Lokman and Zain 2010), user perceptions and acceptance (Boden et al. 2006; Comendador et al. 2015), or the ability for unsupervised learning through user interactions (Serban et al. 2017).

The current work examines how conversational interfaces can systematically alter consumer-firm relationships and how key interface properties (e.g., the capacity to take turns, the extent of system autonomy, the extent of anthropomorphism, and linguistic formality) can impact consumer brand perceptions and choice. Based on four incentive-compatible experiments, we show that consumers perceive a conversational interface as substantially more human-like compared to traditional interfaces, and that this increase in humanness creates more intimate consumer-brand relationships, ultimately enhancing the effectiveness of persuasion attempts.

Study 1 examined how key structural properties of conversational interfaces (i.e., the ability to take turns and the extent of system autonomy) influence their perceived humanness and consumer brand perceptions. Participants (N=226) were randomly assigned to the conditions of a 2 (presence vs. absence of turn-taking) x 2 (high vs. low system autonomy) between-subjects design and completed a simple choice task in a design context. In the turn-taking present condition, the conversational interface interacted in a sequential question-answer exchange with participants, while in the turn-taking absent condition the interface presented all options simultaneously. In the high-autonomy condition, the interface proactively advanced to the next question while in the low-autonomy condition participants controlled the pace of the interaction. We assessed the perceived humanness of the system (e.g., “This configuration system has properties”), 7-point Likert scale; $α_{humans}=.96$) and consumers’ brand perceptions (using a thought-listing task). In support of our theorizing, we find that both turn-taking and high system autonomy significantly increased the perceived humanness of the interface ($M_{Turn\_Taking\_Present} = 4.32, M_{Turn\_Taking\_Absent} = 3.52; F(2, 222) = 10.561, p<.01$; $M_{System\_Autonomy\_High} = 4.15, M_{System\_Autonomy\_Low} = 3.68; F(2, 222) = 4.137, p<.05$). The interaction between these factors was non-significant ($F(1, 222) = 0.06, p>.80$), indicating that they act independently to alter perceived humanness. Furthermore, both turn-taking and high system autonomy led to more favorable brand evaluations ($M_{Turn\_Taking\_Present} = 2.64, M_{Turn\_Taking\_Absent} = 0.53; F(2, 222) = 15.522, p<.001$; $M_{System\_Autonomy\_High} = 0.76; F(2, 222) = 10.202, p<.01$). The interaction was non-significant ($F(2, 222) = 0.212, p=.64$), suggesting that these two properties operate independently.

Study 2 more directly assessed whether a conversational interface is perceived as more human-like and promotes a more intimate consumer-brand relationship compared to a traditional interface. We developed a conversational rental car interface based on the flowXO technology (used across all following studies). 236 regular car rental customers were recruited ($M_{Age} = 37.14, SD_{Age} = 11.26, 49% females) and randomly assigned to either a traditional car rental interface or a conversational interface. Participants in both conditions answered a conversational interface. Participants in both conditions answered a rental task, par-
participants rated the perceived humanness of the system (e.g., “This configuration system has human properties”, 7-point Likert scale; $a_{human}=.96$) and how intimately they felt connected to the brand (e.g., “I feel like AI.Rental really cares about me”, 7-point Likert scale; $a_{brandintimacy}=.92$). In line with our prediction, consumers perceived the conversational interface as significantly more human-like than the traditional interface ($M_{conversational}=4.89$, $M_{traditional}=3.14$; $t(234)=7.654$, $p<.001$). Moreover, they reported greater intimacy with the brand ($M_{conversational}=4.42$, $M_{traditional}=3.91$; $t(234)=2.248$, $p<.001$), with the effect on brand intimacy being significantly mediated by perceptions of humanness (5000 bootstrap resamples; CI95%=[.86;1.59]).

Study 3 investigated whether greater intimacy can be induced by altering the linguistic formality employed by the system (cf. Ludwig et al. 2013). 214 regular car rental customers were randomly assigned to either a traditional booking interface, a conversational interface using a formal communication style, or a conversational interface using an informal communication style. A one-way ANOVA revealed a significant effect on both the perceived humanness of the system ($F(2,214)=26.87$, $p<.001$) and perceptions of brand intimacy ($F(2,214)=4.283$, $p<.05$). Follow-up contrasts revealed that the more informal communication style was perceived as more human-like compared to both the interface using a more formal communication style ($M_{informal}=5.15$, $M_{formal}=4.49$; $t(214)=2.239$, $p<.05$) and the traditional interface ($M_{traditional}=3.11$; $t(214)=7.198$, $p<.001$). The findings for brand intimacy mirrored those on perceived humanness and replicated the pattern of mediation results shown in Study 2.

Study 4 examined the downstream consequences of using a conversational interface on consumer choice. The results show, for instance, that consumers are significantly more likely to accept a costly fuel service upgrade from a conversational compared to a traditional interface ($P_{conversational}=47.4\%$, $P_{traditional}=29.2\%$; $z(257)=2.257$, $p<.05$) and that this effect is amplified when the interface is personalized toward participants (matching participants’ gender and the first letter of their first name) ($P_{personalized}=54.5\%$, $P_{not\ personal}=.44.1\%$). These findings generalize across a range of other rental-car upgrades (e.g., pre-paid fuel option, GPS, wifi) ($P_{conversational}=42.6\%$, $P_{traditional}=25.4\%$; $F(1,157)=10.13$, $p<.001$).

This research is the first to investigate the role of conversational interfaces as “persuasion” instruments in the context of consumer decision making. It shows that such interfaces can systematically alter brand perceptions and consumers’ susceptibility to persuasion attempts. The findings of this research advance our understanding of consumers’ preference construction in that they demonstrate that, compared to using traditional interfaces, expressing one’s preferences through interactive, dialogue-based interfaces with non-human agents systematically alters how consumers respond to market offerings.

**Blaming the Bot: Anthropomorphism Exacerbates Negative Responses from Angry Customers**

**EXTENDED ABSTRACT**

The global chatbot market will exceed $1.34$ billion by 2024 (Wiggers 2018), and chatbots are predicted to power $85\%$ of all consumer service interactions by 2020 (Hinds 2018). Some industry voices suggest chatbots will both improve customer service and reduce costs (De 2018), while others believe chatbots will harm customer service (Kaneshige 2018). Interestingly, many companies choose to humanize their customer service chatbots (giving them avatars and a name). However, little is known about how anthropomorphism influences consumer responses to customer chatbots. When is anthropomorphizing a customer service chatbot a good or bad idea?

Anthropomorphism is the attribution of human-like characteristics to non-human agents and objects (Epley, Waytz and Cacioppo 2007). It can be induced through visual human-like cues, including the use of avatars (virtual characters that can be used as company representatives; Redmond 2002).

Consumers attribute a certain level of agency to anthropomorphic entities, perceiving them to be capable planning and acting in a deliberate manner (Gray, Gray and Wegner 2007; Waytz et al. 2010). Anthropomorphism increases expectations that the agent has abilities such as emotion recognition, planning, and communication (Gray, et al. 2007). These heightened expectations can lead to an expectancy violation if the anthropomorphic entity does not perform in the agentic manner that it’s human resemblance would imply (Waytz et al. 2010). This negative disconfirmation results in feelings of dissatisfaction (Sundar and Noseworthy 2016), ultimately harming purchase intention and company evaluations (Cardello and Sawyer 1992).

Importantly, angry consumers are especially likely to suffer when another’s performance falls short of expectations (Roseman 1984) because anger evokes an action-orientation (Martin at al. 2000). Even incidental anger increases the tendency to hold others responsible for outcomes (Keltner et al. 1993) and respond punitive towards them (Lerner and Keltner 2000). Thus, we propose that for angry customers, chatbot anthropomorphism will harm customer satisfaction and downstream variables, and this negative effect is mediated by expectancy violations. We find support for our hypotheses across four studies.

Study 1 analyzed a dataset from live consumer interactions with a T-Mobile chatbot to examine whether anthropomorphism influenced customer satisfaction. The sample consisted of 1,645,098 consumer inputs from 461,689 unique consumer help sessions, resulting in 34,629 satisfaction ratings between one and five-stars. Automated Natural Language Processing was used to score consumers’ language for social/relational speech, positive/negative emotion, anxiety, anger, and frequency of using the chatbot’s name in conversation (as a proxy for user-perceived chatbot anthropomorphism). The two-stage Ordinal Regression (Heckman Correction for selection to provide a rating) revealed that bot technical failure, and longer conversations increases likelihood of feedback ratings. There was a positive main effect of bot technical failure and consumers’ social language on satisfaction ratings. Importantly, there was a strong negative interaction of anthropomorphism and consumer anger on satisfaction. Thus, anthropomorphism drives positive consumer satisfaction, except in angry consumers, where it had a drastic negative effect.

A series of three follow-up experiments tested this effect under more controlled experimental settings, allowing us to infer a causal-ity and confirm the effect was not being driven by any idiosyncratic features of the chatbot (e.g., gender or expression).

Study 2 tested the causal effects of anger and chatbot anthropomorphism on satisfaction using a 2(Scenario: neutral versus anger) by 2(Chatbot: control versus anthropomorphic) between-subjects design. 197 MTurk participants read a scenario about receiving a broken camera, chatted with a customer service agent to resolve the issue, then rated their satisfaction with the interaction using a 5-star rating system. Those in the anger condition read a scenario designed to evoke anger, while those in the neutral condition read the same scenario with the anger-evoking details omitted. Then, those in the control condition interacted with an “Automated Customer Service” chatbot in a simulated interaction. In the anthropomorphized condition, participants interacted with “Jamie” who was depicted with
a gender- and expression-neutral avatar (confirmed via pretests). ANOVA results demonstrated a significant interaction of anthropomorphism and anger on participants’ satisfaction with the service interaction ($F(1,193)=5.26$, $p=.02$). As predicted, angry consumers reported lower overall satisfaction when the chatbot was anthropomorphic than when it was not ($F(1,193)=33.45$, $p<.001$).

Study 3 used a professionally commissioned chatbot to demonstrate that the negative effect of chatbot anthropomorphism extends to influence company evaluation. 182 MTurkers participated in the 2 condition (Chatbot: control versus anthropomorphic) design. All participants read an anger-inducing scenario about searching for product information (scenario changed from study 2), chatted with a customer service chatbot (manipulated as in study 2), then evaluated the company on four bipolar items (Unfavorable:Favorable, Negative:Positive, Bad:Good, and Unprofessional:Professional; $a=.98$). An ANOVA demonstrated a significant negative effect of chatbot anthropomorphism on company evaluation ($F(1,180)=4.59$, $p=.03$).

Finally, Study 4 demonstrated the negative effect of chatbot anthropomorphism also influences consumers’ purchase intentions and established evidence for expectancy violations as the underlying process. 171 MTurkers participated in the 2(Scenario: neutral versus anger) by 2(Chatbot: control versus anthropomorphic) design. Participants the anger condition read the scenario from study 3; those in the neutral condition read the same scenario without the anger-evoking details. The chatbot manipulations were the same as in study 2 except the anthropomorphized chatbot was depicted using a different gender- and expression-neutral avatar (confirmed via pretests). Participants stated their purchase intentions and answered questions about their perceived expectancy violation (discrepancy between chatbot’s expected and actual performance). An ANOVA demonstrated a significant anthropomorphism by anger interaction on purchase intentions ($F(1,167)=4.29$, $p=.04$). Moderated mediation results (model 8 in PROCESS) demonstrated that in the anger condition, expectancy violations explained the negative effect of anthropomorphism on purchase intention (indirect effect $=-.1839$; 95% CI: [-.3912, -.0023]).

Companies make a deliberate decision of whether or not to anthropomorphize their customer service bots. Yet, four studies suggest that companies should try to gauge whether a consumer is angry before they enter the chat (e.g., through natural language processing, and only present an anthropomorphic bot if the consumer is not angry. Otherwise, they risk lower chat satisfaction ratings, company evaluations, and purchase intentions.

SESSION OVERVIEW

Consumers have many options when deciding how to pay for a given purchase. However, rather than making straightforward economic calculations around financing costs, consumers’ perceptions and behaviors tend to vary across different forms of payment. A significant body of literature explores the effects of payment method on willingness to pay and pain of payment (e.g., Prelec and Loewenstein 1998, Gourville and Soman 1998, Prelec and Simser 2001), but leaves open questions about how payment method can affect other aspects of consumer behavior. In the current session, we aim to identify factors that influence choices across similar payment methods, and examine consequences for interpersonal interactions, as well as subsequent saving and repayment decisions.

Paper 1 (Shah, Bettman, Chartrand, Vohs, and Eisenkraft) investigates how payment method can affect social interactions. The authors show the level of closeness in an interpersonal interaction is affected by whether the person paying uses cash or card. They find when two people are in a desirable or collaborative setting, paying with cash increases interpersonal connection relative to paying with a card. However, the opposite pattern emerges when two people are in an undesirable or competitive setting.

Paper 2 (Sharma, Cryder, and Tully) explores how consumers’ perceptions and behaviors regarding debt change depending on whether the debt is a line of credit or a loan. Debt that is framed as a line of credit (loan) is more likely to be mentally represented and money gained (owed). When framed as a line of credit, participants are more likely to take on debt and less worried about repayment. The findings also suggest that the difference may be explained by differences in how credit cards and loans are marketed.

Paper 3 (Kan, Katz, and Sussman) studies how making large purchases with different financing options can impact perceived financial constraint. The authors find that, relative to paying in a lump sum either at the time of purchase or after a six-month delay, paying in equal monthly installments leads to greater perceived financial constraint and to subsequent differences in saving and spending behavior. This pattern stands in contrast to an ex-ante preference among participants for the monthly payment method, believing it will result in the lowest perceived financial constraint.

Paper 4 (Bechler, Morris, and Huang) shows consumers’ preferred payment method varies depending on the difficulty of justifying the purchase. Consumers are more likely to use cash than a card when making hard-to-justify purchases. This is due to the fact that cards leave a record of the transaction that may be revisited in the future.

Taken together, the four papers in this session address questions surrounding the impact of different payment methods on consumer perceptions and decisions (papers 1, 2, and 3) and which payment methods consumers prefer (papers 3 and 4). We anticipate this session will have broad appeal to scholars interested in financial decision-making, resource constraint, and improving consumer welfare.

Increasing the Pain of Payment Increases Affiliation and Rapport in Collaborative but not Competitive Relationships

EXTENDED ABSTRACT

If one could wish for two gifts that would substantially make life better, having money and forming close-knit relationships would be ideal candidates. Money and relationships, while being able to improve life outcomes, do so by dramatically different routes and mechanisms—and yet have significant overlap as well. For example, there are many instances where we use money as a means to form or strengthen our ties to one another. Yet, the mere concept of money has also been shown to change people’s behavior for the worse, leading to behavior that is antisocial, selfish, and less thoughtful/mindful of others (Amato and Rogers 1997; Bhattacharjee, Dana, and Baron 2017; Vohs, Mead, & Goode 2006).

Recently we have seen large shifts in how consumers pay for transactions, with ‘plastic’ payments occurring more frequently than ever before (Foster, Schuh, and Zhang 2013). Psychologically, this is interesting because more proximal forms of payment (i.e., cash) create more pain of payment, in comparison to more distant forms of payment (i.e., debit cards, vouchers; Gourville and Soman 1998; Soman 2001). There is evidence that increasing the pain of paying at the time of purchase can influence how connected individuals feel towards the product/organization post-purchase (Shah et al. 2016). But can this spillover to our interpersonal relationships? Could the payment used in a social interaction—e.g., whether one treats another person using cash or ‘plastic’—affect how connected and close individuals feel to one another?

We first tested these predictions using a hypothetical dinner scenario. Participants (N = 559) went through a visual scenario in which two individuals meet up after work and go out to dinner. In one photo, participants are shown a picture of the two individuals where they are seated across from one another at the table finishing up their appetizers. In order to manipulate payment form, half of the participants are told that one of the individuals pays for the bill entirely using cash (debit card) along with corresponding picture of a bill with cash (debit card) sticking out of it. Participants are then
assessed how close the two individuals in the scenario are (based on their memory of the one earlier photo), both implicitly by choosing the size of the table that they think is the appropriate length (shorter tables would be perceived as sitting closer) and explicitly via participants to report the physical distance of how close the two individuals were sitting. Participants also then answered questions about their perceived relationship. Paying by cash led participants to rate that two couple was sitting at a shorter table ($p < .01$), physically closer ($p < .001$), and more likely in a romantic relationship, saw each other more frequently, and knew each other longer (all $p < .03$) as compared to paying by cash. These results were mediated by the perceived pain of payment that participants believe that the spender experienced when paying for the bill whereby cash increased perceived pain of paying, subsequently increasing perceived closeness of the two individuals implicitly, explicitly, and relationally. These results replicated across four other studies varying the gender composition, restaurant, and meal.

Does increased pain of payment always lead to more closeness or can more pain decrease closeness in certain cases? In order to better understand the mechanism behind our effects, we ran a quasi-field experiment with dyads ($N = 176$), using a 2 (Relationship Frame: Collaborative or Competitive) x 2 (Payment: Cash or Voucher) x 2 (Spender or Recipient) between-subjects design using multiple measures of interpersonal connection and rapport. Participants arrived in groups of two. Half of the groups were told that they were in a collaborative task, competing with other teams to solve the most anagrams in ten minutes for a prize. The other half of groups were told that they would be taking part in a competitive task, competing with other individuals where the two individuals with the most solved winning a prize. Rewarding the highest two individuals controlled the amount of people who would win across conditions, also ensuring that participants could feasibly view the other person in the experiment with them as a potential resource just as in the collaborative frame. Participants were then told that before they took part in the anagram task, they would have a chance to get to know one another for 10 minutes at the student café. One person (the spender) was given $10 cash ($10 voucher), with the voucher being a less painful payment form, to spend between the two of them on a snack and/or drink of their choice (the dyad could not keep any extra money). Dyads returned and took part in the anagram contest. Experimenters video recorded the interaction during the anagram task measuring physical distance, eye contact, smiling, and whether the pair worked together/helped one another. After the ten-minute timer rang, individuals were instructed to fill out a questionnaire regarding their experience (including explicit affiliation measures of the other participant and a pain of payment question for the spender). 

Taken together, we find evidence that experiencing more pain of payment can increase post-transaction connection when individuals are in desirable or collaborative relationships, but can create greater interpersonal distance reducing post-transaction connection when individual are in undesirable or competitive relationships.

Not all Debt is Created Equal: On the Mental Accounting of Debt Forms

EXTENDED ABSTRACT

In March 2018, Americans’ revolving debt reached over 1 trillion, most of which was credit card balances. At the individual level, 44% of Americans have credit card debt, with an average outstanding balance of $6,600 (Kopf 2019). Many of these consumers view their credit card borrowing as burdensome, with one out of eleven Americans who have credit card debt believing that they will never be free of that debt (Tsosie and El Issa 2018).

Giving the large amounts of consumer credit card debt, we investigated the mental accounting of debt forms. In particular, we examined mental representations of debt in the form of credit (e.g., credit lines), and whether consumers mentally represent these forms differently from structurally similar options such as loans. Although both debt forms offer a liquidity component and a repayment component, we propose and demonstrate that these two forms vary in the extent to which consumers mentally represent them as “debt” (money owed). We show that credit is less likely to be represented as “money owed” as compared to loans. We use this conceptualization to better understand credit usage and repayment, and develop interventions that may mitigate costly financial decisions.

In March 2018, Americans’ revolving debt reached over 1 trillion, most of which was credit card balances. At the individual level, 44% of Americans have credit card debt, with an average outstanding balance of $6,600 (Kopf 2019). Many of these consumers view their credit card borrowing as burdensome, with one out of eleven Americans who have credit card debt believing that they will never be free of that debt (Tsosie and El Issa 2018).

Study 1 was designed to examine consumers’ mental representations of financing in the form of credit versus loans by investigating how they visually represent having access to these debt forms. Participants imagined having additional financing in the form of either a line of credit or a loan. Then, they viewed two visual depictions, with one representing an increase (money to be spent) and one representing a decrease (money owed) of $500. Participants were less likely to represent a line of credit (46.6%) as money owed as compared to a loan (69.2%), $\chi^2(1) = 31.92, p < .001.$

We propose that people mentally represent credit (vs. loans) more as additional money to be spent rather than repaid. If so, online searches for credit cards should be more likely to focus on access to funds and the ability to spend compared to searches for loans. Similarly, online searches for loans should be more likely to focus on the need to repay and repayment terms compared to searches for credit cards. In study 2, we used a Google trends comparison tool to test whether this pattern exists. We found the expected interaction, $B = 67.71, SE = 1.69, t(2009) = 39.96, p < .001.$ While credit cards were searched more often than loans when accompanied by terms focused on access or spending, loans were searched more often than credit cards when accompanied by terms focused on repayment.

In study 3, participants wrote a story about someone who either had a revolving balance on their credit cards or an outstanding balance on a personal loan. Then, they thought about the main character in their story and identify which of eight avatars best represented that character. Four of the avatars were designed to depict characters who appeared to be wealthier (i.e., less indebted) and the remaining four were designed to depict characters who appeared to be poorer (i.e., more indebted). As predicted, participants in the credit condition were less likely to select a relatively poor (indebted) avatar as compared to participants in the loan condition, Wald $\chi^2(1), = 8.90, p = .003.$

Study 4 was designed to examine consequences of consumers’ mental representations of debt. Participants considered an offer for
an all-inclusive vacation, and an offer for either a one-time line of credit or a one-time loan that they could use for the vacation package. All else was held constant across conditions—the intended purchase, amount needed, revolving nature of the debt form, and the interest rate. As predicted, participants were more interested in using the financing offer in the line of credit condition as compared to the personal loan condition, $F(1, 403) = 4.97, p = .026.

Study 5 examined whether these effects emerge when credit is more costly. Participants read about a financing offer for holiday purchases—either for a credit card with a higher interest rate or for a personal loan with a lower interest rate. Despite the credit card financing being more expensive, participants in the credit card (vs. personal loan) condition rated the offer as more attractive, $F(1, 399) = 5.76, p = .017, and were less concerned about repaying the financing, $F(1, 399) = 4.63, p = .032. Further, participants indicated that using financing in the form of a credit card would feel less like money owed as compared to using financing in the form of a personal loan, $F(1, 399) = 19.07, p < .001, which explained the effect of debt form on both interest in using debt and concern over repaying it.

In study 6, we examined whether an intervention aimed at changing consumers’ mental representation would decrease credit card spending. Specifically, we encouraged half of the participants to think of their own credit card as a “loan card.” As expected, participants encouraged to think of their own credit card as a “loan card” were significantly less likely and interested in using their card to make an upcoming purchase, both $p < .001. In addition, participants were more likely to view their credit card as money owed rather than gained, which explained the effect.

Finally, study 7 followed a 2 x 2 between-subjects design that varied debt form (credit vs. loan) and marketing framing (method of spending vs. method of financing). Specifically, participants viewed an offer for either a credit card or personal loan that varied in terms of whether the financial product was described as a form of debt. We found the expected interaction, $F(1, 801) = 4.88, p < .027. Advertising language that described financial products as a form of debt decreased interest in using credit cards, $F(1, 801) = 7.35, p = .007 and had no effect on using financing in the form of loans, $F < 1$.

The Impact of Payment Plans on Feelings of Financial Constraint

EXTENDED ABSTRACT

When purchasing expensive products, consumers are often presented with different financing options. This allows consumers to overcome potential liquidity constraints. We explore a potential consequence of financing choice; namely, influence on financial constraint. Prior research has shown that perceived financial constraint taxes cognitive capacity (Shah 2015; Mani et al. 2013) and is associated with high-interest borrowing (Shah, Mullainathan, and Shafir 2012). However, less research explores the antecedents of perceived financial constraint. We find that payment plans with equal monthly installments result in greater perceived financial constraint overall than paying the full cost in a lump sum, even when the full cost is postponed. Additionally, participants who pay in monthly installments allocate less money when given the opportunity. This pattern stands in contrast to beliefs that monthly financing will result in the lowest perceived financial constraint, and a corresponding preference among participants for the monthly payment method.

In the first study, participants read a hypothetical scenario in which they were planning to purchase a couch and loveseat set for $1,200. Participants were randomly assigned to one of three payment plans; pay the entire $1,200 at the time of purchase (“upfront”), pay $200 per month for six months (“monthly”), or pay the entire $1,200 six months after the purchase (“deferred”). After being assigned to condition, participants proceeded through 12 screens representing a calendar year. In each month, participants were asked how financially constrained they would feel and responded on a scale from 1 to 7 (1 = Not at all financially constrained, 7 = Very financially constrained). Participants were also told they have a retirement plan through their employer and they were asked how much they wanted to contribute to the retirement plan each month.

We analyze perceived financial constraint and retirement contributions during the six-month period from April to September, when the payments are different across conditions. A repeated measures ANOVA tested for differences in perceived financial constraint and retirement contributions. Post-hoc comparisons and planned contrasts revealed that those in the monthly condition felt significantly more constrained than those in the other two conditions ($M_{upfront} = 4.44, M_{monthly} = 4.79, M_{deferred} = 4.34$; (Monthly) vs. (Upfront and Deferred), $p = .04$). Additionally, average monthly retirement contributions were significantly lower for those in the monthly condition ($M_{upfront} = $242, $M_{monthly} = $175, $M_{deferred} = $235; (Monthly) vs. (Upfront and Deferred), $p = .002$). Perceived financial constraint mediated the effect of monthly versus lump sum payments on average retirement contribution ($b = .50, SE = 3.45, 90% CI = [.28, 11.34]) suggesting a causal relationship in which greater financial constraint leads to lower retirement contributions.

In a second study, we tried to replicate the results of Study 1 with a different focal monetary decision, this time in a spending context. Participants received the same information about the couch/loveseat set as in Study 1. Additionally, participants were told to imagine a beverage they like that costs $5. We then asked how many days in each month they would purchase the beverage.

We again ran a repeated measures ANOVA to test for differences in perceived financial constraint and beverage purchases. Perceived financial constraint for those in the monthly condition was significantly higher than those in the upfront condition ($M_{upfront} = 4.22, M_{monthly} = 4.64, M_{deferred} = 4.56$; (Monthly) vs. (Upfront and Deferred), $p = .035$). Average monthly beverage purchases were significantly lower for those in the monthly condition ($M_{upfront} = 8.41, M_{monthly} = 6.17, M_{deferred} = 8.39$; (Monthly) vs. (Upfront and Deferred), $p = .002$). Furthermore, differences in perceived financial constraint mediated the effect of monthly versus lump sum payments on beverage purchases ($b = .60, SE = .29, 95% CI = [.06, 1.18]) suggesting a causal relationship. In this case, higher financial constraint led to lower spending on a discretionary product.

Studies 1 and 2 suggest monthly payment plans cause greater perceived financial constraint than lump sum payments, and influence subsequent spending and savings decisions. A natural question to ask is whether consumers are aware of this ex ante. In Study 3, we described the same scenario regarding the couch/loveseat purchase and explained the three payment options. Then, we asked participants which payment option they would prefer and which would cause them to feel the least financially constrained. The order of the two questions was counterbalanced.

The results showed consumers’ ex ante preferences and beliefs contrast with the findings regarding perceived financial constraint in our first two studies. Approximately half of all participants preferred the monthly payment plan and believed that option would cause them to feel the least financially constrained, compared to about 30% for the upfront plan and 15% for the deferred plan.

The results of this research have important implications for consumer welfare and companies that offer product financing. Initial results suggest that monthly payment plans may lead to greater per-
ceived financial constraint, relative to paying in a lump sum. This is a particularly important finding given that it stands in contrast to participants’ beliefs that monthly payment plans should lead to the least financial constraint. Furthermore, our findings suggest that monthly payment plans may lead consumers to allocate less money to focal financial decisions, including both saving and spending decisions. This work contributes to existing literature exploring the impact of payment methods on pain of paying (Prelec and Loewenstein 1998; Soman 2001) by extending the investigation to perceptions of financial constraint and its consequences. We also contribute to research in scarcity (Shah et al. 2012), showing how constraint can alter the allocation of resources to subsequent savings and spending decisions.

**Eliminating the Paper Trail: Consumers Use Less Trackable Payment Methods for Hard-to-Justify Purchases**

**EXTENDED ABSTRACT**

Imagine you are buying heroin. Your technologically savvy dealer who has a Square card reader offers you the opportunity to pay with cash or debit/credit card. Because this is an illegal transaction and you do not want a record of the purchase that others (e.g., the government) may subsequently see, you likely opt to pay with cash.

This scenario is probably difficult to imagine for a typical ACR attendee. However, most if not all consumers have at one point faced this type of decision—choosing between different payment methods when making a purchase. These purchases elicit various perceptions and feelings. For example, purchases such as a cheap souvenier on vacation or an overpriced bottle of water at the airport, while not illegal, do not make consumers feel particularly proud. Because these purchases are hard-to-justify, they can induce negative feelings such as guilt, shame, regret, or embarrassment. Unlike the purchase of heroin, where there is a need to prevent others from subsequently seeing a record of the transaction, these everyday purchases may induce a psychological need for the consumer to avoid recalling these transactions in the future. Because purchases with cards leave a paper trail, consumers may opt to use cash rather than cards for these hard-to-justify purchases—not to hide these purchases from others, but to hide them from themselves.

Our theorizing connects classic justification literature (Inman and Zeelenberg 2002; Simonson 1989) with past research on inter-temporal choice, which demonstrates that consumers have a strong aversion to future pain and loss (Loewenstein and Thaler 1989; Prelec and Loewenstein 1998). Consumers are increasingly becoming aware of their financial footprint through the constant tracking of their assets, purchases, and bills, and know that they will revisit the transactions they make via trackable payment methods again in the future. Because consumers have a strong aversion to revisiting financial activities that could induce negative feelings, they prefer less trackable payment methods (cash vs. a card) for hard-to-justify purchases to reduce the likelihood that they will revisit these transactions.

Notably, we expect that this effect emerges even though financial statements may not always display the exact names of the items that consumers purchased because consumers generally can recall (or infer) their specific past purchases when seeing the stores’ names on their statements. This was confirmed via a pilot (202 MTurkers) where participants remembered the items they purchased in 88.49% of their card transactions when viewing the transaction descriptions.

Across five studies we found consistent support for our hypothesis that consumers prefer using cash for less justifiable purchases to avoid recalling these purchases. In Study 1, we tested for this relationship using field data from a university bookstore. We categorized 122,940 in-store item purchases from April 1 – May 13, 2017 into 58 purchase subcategories via web scraping, and then had 902 MTurkers rate the justifiability of purchasing items in each subcategory. Controlling for relevant variables (e.g., price, discounts), we found that the harder it was to justify purchasing an item of a given subcategory, the more likely customers were to use cash (vs. card) for the purchase, $p < .001$.

Four lab studies followed up on this result and illustrated convergent validity. In Study 2, 103 university students viewed 10 items sold at the bookstore. Half of the items were hard-to-justify (e.g., foam stadium hand) and half were easy-to-justify (e.g., notebook). Participants were informed that each item cost $5 and indicated whether they would purchase each item with cash or debit card. Participants were more likely to use cash than card for hard-to-justify purchases, $p = .005$. Pretests measuring the justifiability of the items in this study and subsequent studies verified that our manipulations were successful ($p’s < .001$).

In Study 3, 200 MTurkers viewed five pairs of purchases (ranging $5 - $30) that were equivalent in price and purchase location but varied on justifiability (e.g., easy-to-justify: $15 on ibuprofen at a convenience store; hard-to-justify: $15 on candy at a convenience store). Participants were more likely to pay with cash for hard-to-justify purchases than easy-to-justify purchases, $p < .001$.

Study 4 used a similar design as Study 3 and illustrated a mechanism-based boundary condition of this effect. 200 online participants reported how often they tracked the purchases they made on their cards, and viewed eight pairs of purchases that varied in justifiability. Again, participants were more likely to use cash for hard-to-justify than easy-to-justify purchases, $p = .003$. Additionally, there was a significant interaction between justification and frequency of tracking, $p = .002$. For frequent trackers of their card usage (1 SD above the mean) who were more likely to be reminded of a purchase paid by a debit card in the future, the effect of purchase justifiability on payment method was amplified, $p < .001$. However, there was no effect of purchase justifiability on payment method for infrequent trackers (1 SD below the mean), $p = .846$.

Study 5 (1,432 MTurkers) directly manipulated the trackability of the card for the purchase and purchase justifiability (between-subjects). Participants first chose to purchase one of two $10 items from a convenience store (hard-to-justify choice set: large bags of regular vs. peanut M&Ms; easy-to-justify choice set: Advil vs. Bayer pain reliever tablets). Then participants indicated a payment method for the purchase (trackable card condition: $20 bill or a Visa Debit Card; untrackable card condition: $20 bill or a Prepaid Visa Debit Card). Participants in the trackable card condition were informed that the card was connected to their main bank account (like regular debit cards) and they would see a record of this purchase on their bank statement. Those in the untrackable card condition were informed the prepaid card was not connected to their main bank account (like regular prepaid cards in the marketplace) and they would not see a record of this purchase on their bank statement. As expected, we found a significant justification by trackability interaction, $p = .034$: Participants were more likely to use cash for the hard-to-justify purchase when the debit card was trackable, $p = .017$, but were not more likely to use cash for the hard-to-justify purchase when the debit card was untrackable, $p = .535$.

SESSION OVERVIEW
Perceived progress in attaining a goal is a key factor in determining consumers’ subsequent motivation. Gym-goers are more determined to complete their remaining workouts when they feel closer to their goal (Heath, Larrick, and Wu 1999) and coffee drinkers are more likely to complete a coffee loyalty card when they feel closer to receiving a free beverage (Kivetz, Urmisky, and Zheng 2006). This work has found that how much progress consumers perceive they have made towards their goal, rather than the actual amount of progress they have made, is a stronger predictor of their subsequent motivation. Yet a remaining question is what predicts these progress perceptions in the first place? This session joins together four papers that address this question, offering new insights into the antecedents of goal progress perceptions and identifying important consequences for consumer motivation.

The first two papers examine two different biases that consumers are susceptible to when forming goal progress perceptions. Sharif and Woolley explore how categorization can bias goal progress perceptions and resulting motivation. Specifically, in five studies, they find that consumers who perceive their completed and remaining actions to be in distinct categories anchor their estimates of progress on the proportion of categories completed versus remaining, rather than on the absolute amount of progress made, leading them to underestimate their progress at high absolute progress and overestimate their progress at low absolute progress. Rafieian and Sharif examine how the difficulty of initiating a goal biases goal progress perceptions. In five studies, they demonstrate that people perceive they have made more progress on their goals when they complete a goal-relevant task that was difficult to initiate than a goal-relevant task that was relatively easier to initiate.

The second two papers examine how mindset influences goal progress perceptions. Campbell, Pomerance, and Warren demonstrate how goal orientation influences the “progress bias,” the tendency to believe that goal-consistent behaviors have a greater impact on goal progress as compared to goal-inconsistent behaviors. In six studies, they find that consumers who are higher in promotion focus are more susceptible to the “progress bias.” Lastly, Huang and Aaker examine how shifting people to focus on the journey of their goal achievement vs. the destination of their goal achievement influences goal progress perceptions and resulting motivation. In six studies, they reveal that focusing on the goal as a journey leads to a greater likelihood of people continuing behaviors aligned with the attained goal.

In determining whether or not to persist at their goals, consumers often assess how much progress they have made. As demonstrated by this set of papers, these progress perceptions can be influenced by a wide variety of factors, ranging from cognitive biases to consumer mindset. These papers offer insights that can help consumers be smarter about how they monitor their goal progress. As this session integrates research from a wide range of disciplines, such as cognitive psychology and consumer motivation, we expect that this session will attract researchers of various backgrounds, leading to a rich discussion.

The Categorization Bias: The Effect of Categorization on Goal Progress Perceptions and Motivation

EXTENDED ABSTRACT
Categorization has been shown to influence judgments in a wide range of domains (Allen and Wilder 1979; Maddox et al. 2008; LeClerc et al. 2005). However, prior research has yet to explore how categorization influences perceptions of goals progress, an important factor in influencing motivation. Building off of research on unit bias, which demonstrates that people focus more on the unit amount than on the absolute magnitude (Geier, Rozin, and Doros 2006), we propose perceiving completed and remaining goal-relevant activities to be in distinct categories biases goal progress perceptions, such that consumers anchor their goal progress perceptions on the proportion of categories completed, rather than the absolute progress they have made. Because consumers who categorize completed and remaining actions into distinct categories anchor their estimate of progress on the proportion of completed and remaining categories (closer to 50%), they will perceive they made more progress on their goal under low absolute goal progress, but perceive they made less progress on their goal under high absolute goal progress, compared to consumers who do not categorize their actions. Five studies test this prediction.

Study 1 examined how categorization interacts with absolute progress in informing consumers’ progress perceptions in a 2 (Absolute Progress: High vs. Low) × 2 (Categorization: Present vs. Absent) between-subjects design. 801 participants imagined having the same 7 exercises to complete. In the Low-Progress condition, participants imagined completing two workouts, with five workouts remaining. In the High-Progress condition, participants imagined completing five workouts, with two workouts remaining. We manipulated categorization through a similarity manipulation. In the Categorization condition, the exercises were labeled according to the body part they worked out (either upper body or ab workout). In the No-Categorization condition, these exercises were labeled as “workouts.” Afterwards, we measured participants’ goal progress perceptions. Regression analyses revealed the predicted Progress (High vs. Low) × Categorization (Present vs. Absent) interaction on progress.
perceptions ($B = 21.37, p < .001$). Participants in the Low Progress condition reported greater perceptions of net goal progress in the Categorization (vs. No-Categorization) condition ($B = -8.69, p = .016$). On the other hand, participants in the High Progress condition reported lower perceptions of net goal progress in the Categorization (vs. No-Categorization) condition ($B = 12.68, p < .001$).

Study 2 replicated this interaction using a different categorization cue in a 2 (Absolute Progress: High vs. Low) × 2 (Categorization: label vs. no label) between subjects design. 600 participants learned they had 7 workouts to complete. These were described as Set 1 of exercises and Set 2 of exercises in the Categorization condition and were not grouped under a label in the No-Categorization condition. We replicated the predicted Progress × Categorization interaction ($B = 56.45, p < .001$), such that at Low Absolute Progress, participants reported greater progress perceptions in the Categorization (vs. No-Categorization) condition ($B = -20.73, p < .001$), which reversed at High Absolute Progress ($B = 35.73, p < .001$).

Study 3, examined our proposed process by examining the effect of categorization at a medium level of progress. 1203 participants were randomly assigned to condition in a 3 (Progress: High vs. Medium vs. Low) × 2 (Categorization: Present vs. Absent) between-subjects design. Participants in the Categorization condition learned they had 14 exercises to complete that comprised two sets of workouts. Participants in the No-Categorization condition learned they had 14 exercises to complete (no set label). We manipulated progress (Low Progress: 30% of workout completed; Medium Progress: 50% of workout completed; High Progress: 70% of workout completed).

We theorize that participants anchor their progress perceptions closer to 50% in the categorization condition because they feel they have completed one out of two categories of workouts. Thus, if participants’ absolute progress is actually 50% (as in the Medium-Progress condition), the effect of categorization on progress perceptions should attenuate relative to the low and high conditions. As predicted, we found a significant High Progress × Categorization interaction ($B = -5.77, p = .001$) and a Low Progress × Categorization interaction ($B = .56, p = .002$), such that the difference in progress perceptions between the Categorization and No-Categorization conditions was greater for High (vs. Medium) progress, and the difference in progress perceptions between the Categorization and No-Categorization conditions was greater for Low (vs. Medium) progress. Thus, at medium goal progress, categorization (vs. no categorization) had less of an effect on goal progress perceptions relative to High Progress or Low Progress.

Our last two studies examined consequential outcomes of progress perceptions for motivation. Study 4 used similarity as a cue for categorization. 1600 participants completed a series of mental exercises that were not categorized (all math or all verbal exercises) or categorized (some math and some verbal). We manipulated absolute progress by giving participants a choice to continue or quit the mental exercise task after completing three (Low Progress) or eight (High Progress) exercises out of eleven. We replicated the Progress × Categorization interaction on progress perceptions ($B = 7.68, p = .032$). Further, we demonstrate these progress perceptions influence motivation in an incentive-compatible task: we find a Progress × Categorization interaction predicting participants’ decision to complete the remaining exercises ($B = 5.8, p = .012$), such that under Low Progress, Categorization increased the likelihood of completing the remaining exercises relative to No-Categorization, and under High Progress, categorization decreased the likelihood of completing the remaining exercises. Study 5 replicated these interaction effects on both progress perceptions ($B = -5.98, p = .041$) and motivation ($B = 8.56, p = .002$) in another incentive-compatible study in which participants completed a series of actual exercises that also manipulated categorization via similarity.

Overall, five studies demonstrate the effect of categorization between completed and remaining tasks on goal progress perceptions and the downstream consequences for motivation. We suggest consumers who perceive their completed and remaining tasks to be in distinct categories anchor their estimate of goal progress on the number of categories completed, rather than absolute progress made. Further, we demonstrate that these goal progress perceptions reliably influence consumers’ motivation in incentive compatible tasks.

The Difficulty of Task Initiation Affects Consumers’ Perceived Goal Progress

EXTENDED ABSTRACT

Consumer’s perceived progress towards a goal is an assessment of where the consumer stands relative to a desired end state (Huang and Zhang 2011) and can affect subsequent motivation to pursue the goal (Fishbach and Dhar 2005). However, perceptions of goal progress are not always accurate of consumers’ absolute goal progress (e.g., Campbell and Warren 2014). In this research, we explore one factor that biases goal progress perceptions. We demonstrate that consumers perceive they have made more progress towards their goal after completing a goal-relevant task that was difficult to initiate vs. easier to initiate, holding the actual effort in the goal-relevant task constant. We suggest that people misattribute the effort they put into initiating the task to be effort they have put towards the goal itself, leading them to feel like they have made more progress towards their goals than they actually have.

We test these predictions in five pre-registered studies. In Study 1, 403 participants from Amazon Mechanical Turk were randomly assigned to one of two conditions: effort or no-effort condition. All participants were asked to imagine having the goal of becoming fit. Participants in the effort condition were asked to imagine that on a workout day, the bus did not arrive on time, so they decided to wait for the next bus that arrived 40 minutes later (taking 50 minutes total to get to the gym). Participants in the no-effort condition read that the bus arrived on time and their trip to the gym took 10 minutes. All participants then read that they completed all the exercises they had planned to, taking 60 minutes total. Participants were asked how much progress they had made towards becoming more fit from completing the workout. As predicted, participants in the effort condition perceived to have made more progress than those in the no-effort condition ($t (1,401) = -2.191, p = .029$).

In Study 2 ($N = 400$), we sought to see if our findings were replicable in situations when a task was perceived to be difficult to initiate due to internal factors, rather than external factors. Participants imagined they had a goal of becoming more fit. Participants in the effort condition read that they went to the gym despite feeling sluggish, slow, and not in the right mood. Participants in the no-effort condition simply read that they went to the gym and completed their workout. As expected, perceived progress was significantly higher in the effort condition than in the no-effort condition ($t (1,398) = -2.645, p = .008$). This effect was mediated by perceived effort required to initiate the workout (indirect effect = 2.86; 95% CI: .863 to 5.312).

In Study 3, we examined our predictions in a paradigm involving real behavior. Four hundred MTurk participants were asked to type 20 CAPTCHAs and complete a workout task, consisting of four workouts, which would be then rewarded with a monetary bonus. However, the tasks were framed differently depending on condi-

---

1 Similar mediating results were found in the rest of the studies.
tion. Participants in the effort condition were told that the main task was a workout task. However, they would only be eligible to do the workout task if they first typed twenty CAPTCHAs. Participants in the no-effort condition were told that they would be completing two tasks: a CAPTCHA task and a workout task. Thus, in the effort condition, participants should perceive the workout task is more difficult to initiate than in the no-effort condition. As predicted, perceived progress was significantly higher in the effort condition than in the no-effort condition ($t (1,398) = -2.89, p = .004$).

In Study 4 ($N = 806$), we aimed to replicate our effects in an additional real behavior study where the task was difficult to initiate for internal reasons. In the effort condition, participants were asked to recall and write about two times when they wanted to exercise, but they felt sluggish or lacked motivation. Those in the no-effort condition wrote about times they shopped for clothes. Participants were then given the choice to either complete four exercise activities and receive a monetary bonus or leave the study. Participants who opted in ($N = 735; 92\%$ of participants) then rated their perceived progress towards becoming more fit due to completing the workouts. Those in the effort condition rated their progress as significantly higher than those in the no-effort condition ($t (1,733) = -2.68, p = .007$).

We propose that people misattribute the effort they put into initiating the task as effort they are putting towards the goal-relevant task itself, biasing their goal progress perceptions upwards. In Study 5, we aimed to test this prediction by examining if we could moderate our effect by making it salient to participants that they are misattributing the effort in initiating the task. MTurk participants ($N = 1200$) were randomly assigned to a condition in a 2 (salient vs. not-salient) x 2 (effort vs. no-effort) design. This study followed the same design as Study 1, except participants were asked two questions: “how much effort did it take to get to the gym?” and “how much effort would you put into completing the workout session?” before answering the progress perception question in the Salient condition or after answering this question in the Not-Salient condition. As predicted, in the Salient condition, there was no significant difference between the effort vs. no-effort conditions ($t (1,602) = -.666, p = .51$). However, in the Not-Salient condition, replicating our previous studies, participants in the effort condition felt like they have made more progress than those in the no-effort condition ($t (1,599) = -2.02, p = .043$).

We find consistent evidence of a bias that people are susceptible to when assessing their goal progress. Consumers perceive they have made more progress towards their goals when they complete a goal-relevant that was difficult to initiate than easy to initiate, holding the effort of the task constant, because they misattribute the effort in initiating the task to be effort towards the task itself.

**Moderating the Progress Bias: The Role of Goal Orientation**

**EXTENDED ABSTRACT**

Why do consumers often fail to reach their goals? One reason is because they fail to accurately monitor their behavior and regulate their actions when they are not making sufficient progress (Baumeister and Heatherton 1996; Locke and Latham 1990). Accurately monitoring progress is difficult, and consumers tend to think that behaviors that move them toward their goals (e.g., saving $40 or foregoing dessert) have a larger impact than behaviors that move them away from their goals (e.g., spending $40 or eating dessert), a pattern termed the progress bias (Campbell and Warren 2015).

The present research examines whether motivational differences influence the extent to which consumers show a progress bias. The progress bias occurs because consumers generally believe they will reach their goals, and they seek out evidence consistent with this belief (Campbell and Warren 2015). Regulatory focus theory posits that a promotion focus (pursuing goals by trying to attain success as opposed to trying to avoid failure) leads people to focus predominantly on the presence or absence of positive outcomes (Aaker and Lee 2001; Crowe and Higgins 1997; Higgins 1997). Based on this, we propose that a stronger promotion focus will exacerbate the progress bias in goal pursuit. Because perceptions of progress inform the manner in which consumers pursue goals (i.e., whether or not they alter their strategies in goal pursuit), we additionally argue that promotion focus can discourage consumers from means-shifting (i.e., changing their behavior), even when they are not making sufficient goal progress.

Studies 1 and 2 investigated whether promotion focus moderates the progress bias. In study 1, participants evaluated the impact of saving $40 or spending $40 on a money-related goal. Participants rated the impact of the saving/spending on a 9-point scale, and finally completed an 18-item measure of regulatory focus (Lockwood, Jordan, and Kunda 2002). As predicted, a significant interaction between the saving/spending manipulation and the promotion focus measure indicated that the progress bias (the difference in rated impact between saving and spending) was larger for participants with a stronger promotion focus ($\beta = -.40, t(402) = 2.64, p = .009$, partial $\eta^2 = .0170$). In study 2 we manipulated promotion focus by asking participants to complete word stems designed to prime promotion focus (e.g. _gro_th = growth; Wan, Hong, and Sternthal 2009). Participants then imagined either spending or saving $40, similar to study 1. Participants in the promotion focus condition showed a larger progress bias than participants in the prevention focus condition ($F(1, 266) = 5.18, p = .024$, partial $\eta^2 = .019$).

Study 3 tested whether consumers with a higher promotion focus would be less likely to change their means of goal pursuit because they showed a larger progress bias, even if they were not on pace to reach their goals. We gave participants an incentivized goal to accrue a certain number of points by playing blackjack online. Participants played five rounds of blackjack; the outcome of each round was pre-determined so we could control objective progress. Critically, the outcomes of the second and fifth rounds were equal in magnitude but opposite in goal-consistency (a 73 point win and a loss 73 point loss), allowing us to assess the progress bias in subjects as the difference in rated impact between the two rounds. After five rounds, participants chose whether to continue playing blackjack or switch to another means of goal pursuit (another game). We again measured promotion focus. As hypothesized, we found a positive effect of promotion focus on progress bias ($\beta_{promotion} = .16, t(397) = 2.04, p = .042$, partial $\eta^2 = .010$), a negative effect of progress bias on the likelihood of means-shifting ($\beta_{progress bias} = -.11, z = -2.64, p = .008$), and a significant indirect effect (estimate = -.017, SE = .011, 95% BCCI = [.0463, -.0018]).

In study 4 we tested a potential debiasing intervention using an investment game. Before starting the investment game, half of the participants received a de-biasing intervention, instructing them to pay special attention to any negative events. All participants then selected a mutual fund in which to invest, with an incentive-compatible goal of growing their money to a certain threshold. They observed the performance of their investment over a sequence of quarters in which its value increased or decreased. After several quarters, participants decided whether to invest in a different fund or to stick with their initial choice. In order to create an environment that encouraged switching, we controlled returns such that participants were not on pace to reach their goal. As predicted, the debiasing intervention significantly reduced the size of the progress bias ($\beta_{debiasing} = -.42, t = -2.64, p = .009$).
2.36, p = .019), and did so marginally more for participants higher in promotion focus (β_{promotion} = -.28, t = 1.77, p = .077). Additionally, participants with a higher progress bias were less likely to switch to a different mutual fund (β_{progress bias} = -.25, z = 3.98, p < .001). Moderated mediation analysis showed that at one standard deviation below the mean of promotion focus, there was no indirect effect of the debiasing manipulation on participants decision to change mutual funds (95% BCCI = [-.089, .167]). However, at one standard deviation above the mean of promotion focus, the debiasing manipulation increased participants odds of changing to a different mutual fund (95% BCCI = [.047, .374]).

Our research offers a deeper understanding of when and why consumers fail to accurately monitor their goal progress. Promotion focus leads to a greater progress bias by directing consumers’ attention towards goal-consistent information and away from goal-inconsistent information. This has important implications for whether or not consumers alter their strategies when making insufficient progress in goal pursuit.

**Looking Back on a Journey to Derive Growth: Using Conceptual Metaphor to Shape Perceptions of an Attained Goal**

**EXTENDED ABSTRACT**

People pursue goals throughout their lives. Students attend study groups to excel in school, and dieters monitor portion sizes to lose weight. While some of these pursuits may end with failure, many end with success—the goal is attained.

How do people perceive goal progress that has successfully reached 100%? And how do they behave afterwards? Reaching 100% on a goal allows individuals to disengage from behaviors directed at achieving this specific goal (Ferguson & Bargh, 2004; Förster, Liberman, & Higgins, 2005). This postattainment disengagement is functional, allowing people to focus on other goals deemed important (Gollwitzer, 1999). However, disengagement can also be detrimental, since goal-congruent behaviors are often beneficial in and of themselves. Consider, for instance, those who achieved a weight-loss goal but begin eating poorly again, or students who completed their education but stop acquiring knowledge.

We focus on goals that can benefit from continuous engagement, such as fitness and learning goals, and explore the use of conceptual metaphor—a powerful, immersive cognitive tool that shapes people’s perception of an experience without changing the experience itself (Keefer et al., 2011; Lakoff & Johnson, 1980). We show that perceiving an achieved goal as a journey that one has just completed (compared to an alternative metaphor of having reached a destination, or no metaphor at all) encourages continuous goal-aligned behaviors. We further demonstrate that this positive effect occurs because perceiving an attained goal as a completed journey heightens the feeling that one has indeed grown from the previous goal-unattained state into the present goal-attained state, increasing people’s intrinsic motivation to continue these goal-aligned behaviors (Ryan & Deci, 2000; Dweck & Leggett, 1988; Paunesku et al., 2015).

Study 1 tested the effect of journey metaphor in shaping students’ perception of their attained academic goals. We asked 210 college students who had recently attained an academic goal to describe their experience and the actions they took to complete this goal. We then randomly assigned them to either a journey metaphor, a destination metaphor, or a no-metaphor control condition: “Please take a moment to think about this goal you just successfully attained. Please think about how this experience of attaining this goal is like completing a journey [reaching a destination].” Participants did this thought exercise while looking at a visual that depicted their goal attainment as a completed journey [a reached destination], with the word “journey [destination]” highlighted on the path [the end point of the path] accordingly. Participants in the control condition did not do any metaphor practice. Students reported on three 7-point scales how likely they were to continue each of the three goal-aligned behaviors they reported earlier. Two weeks later, we sent out a follow-up survey to capture how much these students had put into each of the three goal-aligned behaviors in the past two weeks.

We found that when participants were guided to perceive the attained academic goal as a completed journey, they were more likely to continue goal-aligned behaviors (M = 5.86, SD = 1.18) than those using a destination metaphor (M = 5.38, SD = 1.16) and those in the control condition (M = 5.49, SD = 1.43, t(207) = 2.28, p = .024; the latter two conditions were not significantly different. The results after two weeks were consistent with the behavioral tendency reported at time 1. We also replicated this pattern in Study 2, in which 200 adults who had attained a fitness goal chose between 1-month unlimited access to an in-home fitness program or to a comedic relief program. When participants were guided to perceive their 100%-attained fitness goal as a completed journey, they were more likely to choose the fitness program that would help maintain their fitness level than those using a destination metaphor and those in the control condition, t(211) = 3.96, p < .001; the latter two conditions were not significantly different.

Study 3 launched a seven-day food diary program and manipulated the metaphor practice that dieters went through after reaching 100% on their dieting goal (journey, destination, and no-metaphor control). Further, we measured dieters’ perception of personal growth from their completed goal. When dieters perceived the attained dieting goal as a completed journey, they were more likely to continue goal-aligned behaviors than were those using a destination metaphor and those in the control condition, t(262) = 2.93, p = .004. Importantly, this positive effect of journey metaphor occurred by increasing dieters’ feelings that they had indeed grown into the present goal-attained state; mediational pathway through growth = .1412 (95% CI = .0599 to .2235).

Study 4 further verified the driving role of the perception of growth among college students who were about to initiate a three-part financial learning program versus those who just completed this program. We found that for students who had just completed the financial learning program, perceiving this achieved goal as a completed journey helped them look back to derive a sense of growth, which led them to spend more time learning about investing; mediational pathway through growth = 41.20 (95% CI = 28.2039 to 57.2856). In contrast, for students who had not yet started this learning program, the journey (vs. destination) metaphor motivated learning by helping them derive greater continuity to their ideal future identity, replicating the findings documented in Landau et al. (2014).

Study 5 employed a 10-day walking program and captured exercisers’ actual behavior of continuing tracking their walking for another three days after the completion of the program. This study underscored the importance of perceiving a goal as “100% complete” in inducing the positive effect of journey metaphor. Lastly, Study 6 tested our hypotheses among executives who graduated from an executive education program in Africa. Three on-site interviewees executed a 30-minute individually-guided thought practice (journey vs. destination metaphor) during the graduation ceremony; a cohort was excluded from this practice to serve as a control group. Executives who described their achieved business-learning goal as a journey were more likely to continue goal-congruent behaviors even six months after graduation.

SESSION OVERVIEW

In-store promotions are frequently encountered marketing tactics. Yet much of the research on in-store promotions has been managerially in nature, examining the effects on manufacturers (e.g., brand substitutions) and retailers (e.g., spill over sales to other categories). In contrast, this session focuses squarely on the consumer and asks: beyond purchase, how do consumers respond to different types of in-store promotions? Specifically, the papers examine how consumers respond to different pricing strategies (paper 1), promotional displays (paper 2), pro-social appeals at check-out (paper 3), and in-store promotional events (paper 4). Further, the papers explore diverse responses to promotions such as store price image (paper 1), attitude towards the timing of the promotion (paper 2), as well as donations (paper 3), FOMO (fear of missing out) and willingness to recommend the brand (paper 4). Jointly these papers highlight novel and interesting consumer responses to a variety of in-store promotional activities.

Sheehan, Hamilton, and Chellappa examine consumer responses to everyday low price (EDLP) and high-low (HILO) promotion strategies. Prior investigations exposed respondents to prices simultaneously across stores and found lower price perceptions for EDLP promotions. In contrast, these authors exposed consumers to prices sequentially (by store), which may better reflect how consumers encounter promotions in real life. In contrast to previous work, they find lower price perceptions for HILO stores, an effect that strengthens when discounting familiar brands.

Dutton and Diehl demonstrate that in-store thematic promotional displays trigger the generation of prospective event markers (i.e., thinking of things that may occur between encountering the promotion and the promoted event). Timewise, consumers anchor on the event being promoted for event-related markers, but for event-unrelated markers they anchor on the day they encounter the promotion. This temporal anchor affects attitudes towards early promotions, which are more positive for later (vs. earlier) anchors.

Hmurovic and Lamberton examine how consumers respond to retailer-initiated charitable appeals at check-out. They focus specifically on how observing another’s prosocial decision affects consumers responding to the same appeal. Their results show that the speed of an observed donation can chill consumer generosity: observing a very fast donation refusal is inferred as being an easier decision, consequently reducing how much consumers give.

Rifkin, Chan, and Kahn examine how consumers react to in-store experiential promotions that they did not attend, but learn about later (e.g., through social media photos). They find that similar to social events they missed, missing out on in-store events can also trigger FOMO. Further, for those less connected to the brand, highlighting promotional events they missed increased willingness to recommend the brand.

Reflecting the conference theme of expanding wisdom, this session sheds new light on in-store promotions by examining a range of novel consumer reactions to a variety of in-store promotions. All papers are at an advanced stage with multiple studies completed. We expect this session to generate significant interest among researchers studying decision making in retail environments, but also those interested in pricing, timing and event markers, brand experiences, and pro-social behavior.

When is HILO Low? Price Image Formation Based on Frequency versus Depth Pricing Strategies

EXTENDED ABSTRACT

When managing prices, retailers must concern themselves with how their prices affect customers’ individual purchase decisions, but also with how those prices in aggregate affect the retailer’s price image: its overall reputation for pricing. One factor that affects price image is the distribution of a store’s low prices relative to other retailers. Specifically, whether a store has a small price advantage on many items—a frequency strategy—or a large price advantage on just a few items—a depth strategy—affects how consumers feel about its prices overall, relative to its competitors.

An important finding from research on this topic is that consumers tend to form lower price images of retailers with small, frequent relative price advantages than they do of retailers with large, infrequent price advantages. Even when two retailers have the same total price for a basket of goods, or the same average price for an item over time, consumers tend to assume that stores with frequent, shallow price advantages have lower prices overall. Alba et al. (1999) dubbed this the “frequency advantage,” and it has proven to be a notably robust finding (Alba et al. 1994; Alba et al. 1999; Danziger, Hadar, and Morwitz 2014; Lalwani and Monroe 2005).

One limitation of this previous research is that all of it has been conducted in experimental settings where participants were given the prices of frequency and depth stores simultaneously. For example, in several experiments by Alba and colleagues (1994), participants were presented with a list of 60 grocery items, with the prices of each item at two different stores listed side-by-side. Similarly, in studies by Danziger, Hadar, and Morwitz (2014), participants were shown 100 weeks of pricing data for the same product (package of Portobello mushrooms) at two stores, with prices for both stores shown side-by-side, one week at a time.

Advances in Consumer Research
Volume 47, ©2019
While it is not hard to think of settings where consumers might directly compare prices across stores (e.g., comparing weekly circulars, using price comparison apps or websites), the current research is predicated on the assumption that direct comparison across stores is not the only way that consumers encounter a store’s prices. We argue that the context in which prices are encountered—simultaneously across stores vs. separately, one store at a time—has important implications for how consumers translate frequency and depth pricing strategies into a retailer price image. In particular, we suggest that the frequency advantage typically identified by previous research (Alba et al. 1994; Alba et al. 1999; Danziger, Hadar, and Morwitz 2014; Lalwani and Monroe 2005) may be less likely to occur when consumers encounter prices separately, store-by-store, rather than simultaneously across stores.

Historically, the influence of frequency and depth pricing strategies on price image has been investigated in two ways: by showing experimental participants a basket of prices at a single point in time (e.g., Alba et al. 1994) or intertemporally, by showing participants the prices of an item or items as they change over time (e.g., Alba et al. 1999). We wanted to test our proposed theory in both paradigms. Therefore, our first two experiments used a very similar design, but replicating across both the basket of prices approach (Experiment 1A), and the intertemporal approach (Experiment 1B). Experiments 1A and 1B used within-subjects designs, in which participants were exposed to the prices of both stores, one at a time, before making their evaluations.

In Experiment 1A, participants were shown the prices of a list of 40 items at two stores (4 brands in each of 10 categories). One store had small price advantages on 33 of the items (frequency store) and the other had larger price advantages on the remaining 7 of the items (depth store). The total price of all 40 items at both stores was the same. In Experiment 1B, participants saw the weekly prices of 5 brands available in one category (peanut butter) across 16 weeks, 8 weeks at each store (alternating each week). In the frequency store, 4 of the 5 peanut butter brands were \$2.20 lower each than the depth store, but one of the 5 brands was \$0.80 cheaper at depth store. Thus, each week, the total price across the peanut butter category was the same at both stores, and the same from week to week. The results were consistent across the two experiments: in contrast to the frequency effect previously identified, when participants were shown the prices first at one store and then the other, they consistently thought the prices were lower at the depth store than at the frequency store.

Experiment 2 replicated the results of Experiment 1A using a between-subjects design, in which participants viewed the prices at only one store (frequency or depth) before making their evaluations. While extending to a between-subjects design may seem like a trivial innovation over previous work, in fact, previous theories cannot account for price image formation when consumers are exposed to the prices at just one store, rather than being able to explicitly compare across stores.

Experiment 3 examined a theoretically-derived moderator of the effect. Specifically, we have argued that the relative price image advantage enjoyed by depth-stores depends on how easy it is to assess the value of those price advantages. That is, when familiar brands are discounted against other familiar brands in a category, it will be easier for consumers to evaluate the discount. If this account is accurate, then we should expect that the effect will be reduced when consumers are evaluating the prices of unfamiliar brands as they will have no way to evaluate whether a price is attractive or unattractive. Experiment 3 tested this moderator by examining the effect of depth vs. frequency pricing on price image in the context of both familiar and unfamiliar brands. Experiment 4 examined the effect in a more externally valid setting, as participants were asked to shop for products in a store mock-up, one that used real products, store shelving, and price tags. In this context, the central effect was again replicated: when the store used depth pricing, the result was a lower price image than when the store used frequency pricing.

Christmas Promotions in September – What Happened to Halloween? The Effect of Prospective Event Markers on Attitudes Towards Promotions

EXTENDED ABSTRACT

In 2017, Target announced that all promotions would have a Thanksgiving theme during November, responding to requests not to “go right into Christmas” (Associated Press 2017). The early appearance of holiday-themed promotions has been lamented as “holiday creep” in popular culture, however it is unclear whether these attitudes are held widely and if so, what causes these attitudes.

We argue that promotions tied to future events spontaneously cause people to think about events and actions that may occur between encountering the promotion and the promoted event (prospective event markers). Prior literature focused predominantly on how the number of retrospective event markers, i.e., events that did occur after an event, affects time perception (Zauberman et al. 2010, Ahn, Liu and Soman 2009). Prior work on prospective event markers is sparse and has focused on unrelated event markers’ effect on time perception (May 2017).

What remains unknown is whether consumers spontaneously generate prospective event markers and whether these markers affect attitudes towards the timeliness of the promotion, an important and overlooked consumer response. We propose that spontaneously generated prospective event markers carry a temporal dimension which affects attitudes toward the promotion. We expect event markers to be temporally anchored on either the promoted event (related markers) or the day encountering the promotion (unrelated). Subsequently, consumers anchored further in the future may be more accepting of an “early” promotion, than those anchored more in the here and now. We test these predictions in four studies.

Study 1 provides initial evidence that consumers spontaneously generate prospective event markers when encountering thematic promotions and that the type of event marker (related vs. unrelated) can affect attitudes towards the promotion. M-Turk participants (N=305) saw a picture of a Valentine’s Day display and imagined going to the store that day (21 days before Valentine’s Day). Participants first listed anything that came to mind when seeing this display and then indicated their attitudes towards the promotion on a scale from “too early” (1) to “too late” (7), with the midpoint (4) labeled as “at the right time”. They then reported their relationship status and classified each listed thought as related or unrelated to Valentine’s Day.

Most participants (96%) spontaneously listed a related marker and almost half (47%) listed an unrelated marker. On average, people generated more related (M=4.52) than unrelated (M=1.27) event markers (F(1,304)=223.75, p<.001). Given this imbalance, we regressed attitude towards the promotion on whether a related marker was listed (no = -1, yes = 1), an unrelated marker was listed (no = -1, yes = 1), and controlled for relationship status (no = -1, yes = 1). Being in a relationship (β=13, F(1,301)=4.22, p=.041) and listing a related marker were associated with more positive attitudes (β=.33, F(1,301)=4.48, p=.04), however, unrelated thoughts did not have a significant effect (F<1). In order to add greater balance and to rule out any reverse causality we manipulated type of event markers in subsequent studies.

In study 2, M-Turk participants (N=339) were randomly assigned to a 2(Marker number: One/Four) x 2(Marker type: Unre-
lated/Related) between subjects design. Participants saw a picture of a July 4th promotion and imagined going to the store that day (27 days before July 4th). They listed either one or four events that were either related or unrelated to July 4th. They reported their attitude towards the promotion and indicated when each event would occur and whether they planned to celebrate July 4th or not, which we controlled for in all analyses.

For comparability, we use the distance of the first listed event marker from the study date to examine marker timing. Plans to celebrate July 4th did not affect the marker timing marker (F<.01). As predicted, the date of related event markers was closer to July 4th (M=19.26 days), while unrelated event markers (M=13.60 days) were anchored closer to the promotion date (F(1,334)=45.90, p<.001). Unexpectedly, the first marker listed in the one marker condition (M=17.34) was anchored closer to the holiday than in the four marker condition (M=14.77, F(1,334)=6.75, p=.01). The interaction was also significant (F(1,334)=7.85, p<.01), indicating that the difference between related and unrelated markers was larger in the four (F(1,334)=41.33, p<.001), compared to the one marker condition (F(1,334)=8.82, p=.01).

Unsurprisingly, those who planned to celebrate July 4th had more favorable attitudes (b=.19, F(1,334)=11.53, p<.01). Importantly, participants who were assigned to list related markers had a more favorable attitude towards promotion timing (M=3.86) than those who listed unrelated markers (M=3.62, F(1,334)=5.50, p=.02). Neither the number of markers listed (F<1.70), nor the interaction (F<1) were significant. Also, as predicted, the timing of the marker mediated the relationship between marker type and attitude for the one marker (b=-.0218, CI95[-.0620,-.0005]) and marginally for the four marker condition (b=-.0525, CI95[-.1105,.0052]). In a separate study we replicate these findings including the mediation in a non-holiday promotion context.

Study 3 further explored the focal effect across two additional holidays. M-Turk participants (N=422), with plans to celebrate both Halloween and Thanksgiving, were randomly assigned to a 2(Type: Unrelated/Related) x 2(Holiday Replicate: Halloween, 33 days in advance/Thanksgiving, 55 days in advance) between subjects design. Since type of holiday did not interact with the manipulation, we collapsed across holidays in all analyses. Procedures followed those of the study 2.

Replicating study 2, the first unrelated event marker listed occurred closer to the date of the promotion than the first related event marker (M_unrelated=23.49, M_related=30.52, F(1,420)=17.14, p<.001). There was no direct effect of the type of marker on the attitude towards the promotion (F(1,420)=1.70, p=.19), however, timing of the marker significantly mediated the relationship between the type of marker mentioned and the attitude towards the timeliness of the promotion (.1015, CI95[-.1588,.0529]).

This research is the first to examine the relationship between promotions, prospective event markers, and attitudes towards a promotion. We find that related and unrelated event markers are anchored on different points in time, which affects attitudes towards a promotion. Research in progress further examines the effect of relevance of the holiday being promoted.

Waiting and Watching: The Effects of Observing Others’ Point-of-Payment Prosocial Decisions

EXTENDED ABSTRACT

Imagine watching the grocery shopper ahead of you complete their transaction. A request appears on the shopper’s payment screen (“Would you like to make a donation to the local food pantry?”) and while you wait, you see them respond “Yes” or “No.” When you reach the checkout, the same charitable appeal appears. Does your prosocial response depend on whether the previous shopper donated? Does it matter how quickly they made their donation decision?

We propose that the answer to the first question should likely be “it depends.” When we observe another consumer’s choice, their selection becomes a “social default” that we subsequently imitate (Huh, Vosgerau, and Morewedge 2014). However, observing behavior deemed inappropriate or undesirable (as is selfish behavior; i.e., Berkowitz 1972) does not produce consumer mimicry (Mcferran et al. 2010). Further, negative (“hating”) behaviors prompt weaker inferences than do positive (“loving”) consumer behaviors (Gershoff, Mukherjee, and Mukopadhyay 2007) and are, therefore, less diagnostic. Consequently, we predict that consumers who observe others refuse to donate will feel little need to mimic this choice – the observed “No” will not necessarily determine whether they donate or not.

However, in such cases the speed of the observed decision may still shape consumers’ donation amounts. Consumers make critical inferences based on decision speed (e.g., Critcher, Inbar, and Pizzaro 2013; Kupor et al. 2014; Srivastava and Oza 2006), perceiving the speed as particularly diagnostic at temporal extremes (e.g., very quick = less difficult; very slow = greater accuracy; Van de Calseyde, Keren, and Zeelenberg 2014). Based on this, we predict that merely observing the person in line ahead of us choose not to donate won’t persuade us to take the non-normative step of turning down an in-store charitable appeal; however, to the extent that their very fast or very slow decision speed suggests confidence, observing their refusal may nevertheless chill our generosity. Analytically, we thus predict that when a consumer observes another consumer refuse a prosocial appeal, we will see a nonlinear influence of observed decision time on the observer’s subsequent donation amount.

In study 1, participants (n=306 MTurkers; 44.12% male) imagined observing another shopper at a self-checkout station respond to a payment touch-screen donation request. Participants read that they were able to observe the prior shopper’s decision (Yes/No; randomly assigned) and that they had to wait for this decision to be made (between 1 second and 10 minutes:59 seconds; randomly selected). Afterwards, participants indicated their own donation decision upon reaching the checkout (Yes/No), with donors reporting their donation amount. Controlling for income, we see that although the quadratic interaction (speed x outcome) did not impact donation likelihood (r=1.14, p=.255), it did impact donation amounts among those who donated (r=2.13, p=.036). Consistent with our theory, observing fast (between 1 and 65 seconds; p’s ranging from .054 to .099, respectively) donation refusals (r=.2-2.4, p=.027), but not acceptances (r=.39, p=.697), reduced size of donors’ donations. It appears that this negative effect on donation amount also appears in the case of very slow refusals (>666 seconds, p<.10; >942 seconds, p<.05), but these speeds lay outside the study’s manipulated range.

In study 2, we examine whether decision ease inferences account for the nonlinear influence of decision duration using a consequential paradigm that mirrors the common retail check-out context. Lab participants (n=132 students; 50.77% male) learned that one person (per session) would receive $10. Each participant considered donating a portion of their earnings to a local animal charity. Before responding to the donation request, participants waited a randomly-determined amount of time (between 3 seconds and 3 minutes) while another person purportedly made their donation decision (Yes/No; randomly assigned; displayed on-screen). Participants then responded to the charitable appeal, with donors indicating donation amount. Participants reported inferences regarding the other person’s deci-
Before testing these hypotheses in the retailing environment, we ran lab experiments with simulated missed events. Prior research has established that brand relationships are similar to social relationships (Aaker et al. 2004), and since our participants are students, we focus on missed social-group events at school as a surrogate for retailing events involving a brand community. Further, because previous research has suggested that FOMO has negative implications on well-being (Alt, 2015; Baker et al., 2016; Oberst et al., 2017, Rifkin et al. 2018), we begin by validating these intuitions.

In Study 1 (n=191), participants imagined that they had chosen to attend a concert and therefore missed a local barbeque with a friend scheduled at the same time. There were three conditions. In the “no photos” and “own group photos” conditions, members of the participant’s social group attended the barbeque; in the “other group photos” condition, the friend’s family members attended the barbeque. In both “photos” conditions, participants imagined checking social media while at the concert and seeing photos of the missed barbeque.

As predicted, seeing photos from a missed event that included one’s own friends evoked FOMO, which in turn reduced enjoyment at the concert. Specifically, compared to the no photos condition, viewing missed-event photos involving one’s own social group significantly reduced current-event enjoyment (M = -.59, p = .009). However, viewing missed-event photos involving another social group (the friend’s family, M = -.33) had no impact on current-event enjoyment, relative to the no photos condition (M = -.21, p = .406). Further these results were mediated by FOMO, such that missed-event photos of one’s own group generated the greatest FOMO, which consequently reduced enjoyment.

In Study 2 (n=240), we tested the moderating effect of an individual’s anxious attachment style, which refers to the confidence one has in the relationship bond (Fraley & Shaver 2000). Using a similar procedure to Study 1 (without the “other group photo” condition), participants were randomly assigned to a “photos” or “no photos” condition, and an anxious attachment scale was collected (Wei et al. 2007). We replicated the main effect: viewing (vs. not viewing) missed-event photos significantly undermined current enjoyment (M_{view_photos} = -.62 vs. M_{no_photos} = .01), and this was qualified by the predicted viewed photos × anxious attachment interaction (b = -.23, p = .001). Viewing the missed-event photos reduced ongoing experience enjoyment for those higher in anxious attachment, but not among those with lower levels of anxious attachment.

Finding support for the basic hypotheses, we conducted a field study (n=278) with a Lululemon pop-up store on campus. In phase one, we emailed participants a survey about their connection to Lululemon and invited them to an in-store yoga event the following week. Our interest was in the students who did not attend the event. In phase two (after the event), participants navigated to the local Lululemon’s social media page and were randomly assigned to view either photos of event attendees or of Lululemon merchandise. Then, they completed a survey that included our primary DV, NPS (the Net Promoter scale).

We predicted that the social photo condition would evoke more FOMO. Further, we predicted those with a high connection to the brand would react to the FOMO generated by the social event photos as they would be more likely to attend the event and be like those featured in the photos (following results from Study 1). We then predicted they would compensate for these negative feelings by reinvesting in the brand (i.e., report higher NPS).

We found mixed support for our hypotheses. FOMO in the social-photos condition (M=2.61) was higher than in the merchandise-photos condition (M=2.31), but the difference was not significant.
(p=.13). There was a significant photo type × self-brand connection (to Lululemon) interaction on NPS (p=.03); however, the results were opposite from predicted. Viewing social photos increased NPS (vs. merchandise photos) among those less connected to the brand. For those more connected to the brand, merchandise photos increased NPS (vs. social photos).

Speaking with the Store Manager, we identified a potential reason post hoc for the findings. The Store Manager believed (but did not have hard data) that highly connected consumers did not typically attend store events; the events were primarily attended by less connected members of their brand community (contrary to our a priori beliefs). Thus, our actual results are consistent with the manager’s intuition: FOMO-inducing social photos made those who may have identified with the photographed event attendees (here the less-connected members of the Lululemon community) more likely to recommend Lululemon in the future (higher NPS). Similar to Study 2, people less connected to Lululemon, like our anxiously-attached lab participants, were more susceptible to feelings of FOMO. While in Study 2, we observed reductions in well-being, in this field study, participants seem to have compensated for these feelings of disconnection through positive WOM, consistent with prior work (Packard & Wooten, 2013).

SESSION OVERVIEW
How can the field of consumer behavior help consumers better manage their monetary resources? This session brings together four papers that examine biases in consumer money management that have significant implications on spending and investment decisions. While some prior consumer research has demonstrated that consumers do not always perceive and use money in line with standard economic assumptions (e.g., Gourville 1998; Raghubir and Srivastava 2002), the cognitive elements and drivers of these biases remain underexplored. In line with the conference theme of “Becoming Wise,” this session contributes to the understanding of financial wisdom by examining documented biases in the consumer financial decision making literature and expands financial wisdom by clarifying the cognitive processes underlying these biases.

The first two papers revisit two well-documented biases in money management - opportunity cost neglect and the magnitude effect - and broaden our understanding on these biases with process tracing data. Smith, Spiller, & Krajbich set the stage by revisiting opportunity cost neglect. Using eye-tracking data, they show that visual attention to opportunity cost reminders might underlie the consumer tendency to neglect opportunity cost in purchase decisions. Lee, Reec, & Johnson examines how comparative search processes, such as a tendency to consider relative differences in price, contributes to the magnitude effect in intertemporal choice. Using mouse-tracking data, they show that a search strategy that facilitates monetary attribute comparisons is linked to relative thinking and to the subsequent inconsistency in valuation of objectively same price gap across numeric magnitudes of price. The last two papers report new biases in money management. Raghubir & Santana uncover a novel factor that leads to inconsistencies in valuation of the same monetary stimuli: the subjective value of the form of the source of money transfers to its new form. Accordingly, for example, gift cards are spent differently as a function of whether they are purchased using cash, credit cards, airline miles or loyalty points. Trueblood & Sussman uncover a novel motivational bias that influences investment decisions. They show that people generally have a positive outlook on the future and that these optimistic views can serve as reference points, increasing preferences for riskier savings accounts.

Taken together, the present findings complement and advance our understanding of biases in consumer money management behaviors. This topic will benefit from a lively discussion on implications of biases on consumer welfare as well as on the interventions that will debias consumers and help them use monetary resources to their best interest. The primary audience for this session will be basic and applied researchers interested in resource management, financial decision making, and process tracing methods.

The Role of Attention in Opportunity Cost Neglect
EXTENDED ABSTRACT
Choices necessitate opportunity costs: choosing one option means foregoing another. Despite this self-evident economic fact, consumers often neglect their opportunity costs (Frederick et al. 2009; Legrenzi, Girotto, & Johnson-Laird 1993; Jones et al. 1998). As a result, simply reminding consumers that opportunity costs exist (i.e., that they could use their time or money for another purpose) can change consumer choices, typically by reducing the likelihood of spending resources. Making opportunity costs more accessible in memory or increasing resource constraints can increase the likelihood that consumers consider them (Spiller 2011). That is, there is a change in the considered (and subsequently, accumulated) support in favor of not purchasing.

A potential mechanism for this shift in evidence is visual attention. Past research has demonstrated a causal role of visual attention in choices (Armel et al., 2008; Gwinn et al., 2019; Mormann et al., 2012; Pärnamets et al, 2015). Specifically, attention amplifies incoming evidence about the currently-fixated option (Smith & Krajbich, 2019). Therefore, based on this previous research, we hypothesize that the differences in purchase rates are driven by (1) a larger amount of attention given to the explicit opportunity cost and/or (2) a larger impact of attention to the explicit opportunity cost, either way resulting in lower purchase rates.

In this preregistered study, we endowed participants (N = 50) with $4 at the beginning of the study and informed them that one of their choices would be implemented at the end. First, subjects stated how much they would be willing to pay for each of 144 food items. Then, they made 200 incentivized purchase choices (separated in two blocks of 100 trials each) about these food items. Specifically, on each trial, subjects saw a picture of one food item on the screen. After 1 second, the food disappeared and two options appeared on the screen: a “buy” option and a “do not buy” option. Crucially, we manipulated the framing of the “do not buy” option. For one block of trials, the options were labeled “Buy Food for $X” and “Do Not Buy Food for $X” (the implicit opportunity cost condition). For the other block of trials the options were labeled “Buy Food for $X” and “Keep $X” (the explicit opportunity cost condition). The order of the blocks was counterbalanced across subjects. Each price was randomized to take a value between $0.50 below a subject’s WTP for that item and $0.50 above a subject’s WTP for that item.

Importantly, the two “do not buy” options lead to identical outcomes: the subject chooses not to buy the food at the given price. However, the results suggest that subjects do not treat them as identical options. Consistent with prior research, there was a significant difference in the proportion of trials on which participants chose to buy (b = -0.078, se = 0.019, t(49) = -4.06, p < .001), signifying that the proportion of trials on which participants purchased was about 8
percentage points lower when opportunity costs were explicit rather than implicit. To investigate a potential mechanism for this finding, we examined the eye-tracking data. For these analyses, we constructed a single index for each of our measures for each individual. In particular, we averaged each individual’s choices and (log-transformed) dwell time durations across trials within block, resulting in one measure of choice and one measure of attention for each person in each block. We then subtracted the mean of the implicit trials from the mean of the explicit trials.

The effect of explicit opportunity costs on purchases was reflected in attention, that is, the difference in logged dwell times to the Buy vs. Not Buy option (\( b = -0.038, \text{se} = 0.015, t(49) = -2.47, p = 0.017 \)), indicating that making opportunity costs explicit increased attention to the “do not buy” option relative to the “buy” option. There was a significant indirect effect of condition on purchase through relative attention (\( b = -0.034, 95\% \text{CI based on 5,000 bootstrapped samples:} [0.067, -0.007] \)) indicating that the shift in attention partially accounted for the effect on purchase. A significant direct effect remained (\( b = -0.045, \text{se} = 0.015, t(48) = -3.05, p = 0.004 \)), indicating that the shift in attention did not fully account for the shift in purchase rates.

We also examined repeated measures analyses of participants’ choices. Here, we accounted for dependent observations by bootstrapping subjects rather than individual observations and we also controlled for the relative value (WTP – Price) of each trial as a strong covariate of choice. Additionally, we allow for the indirect effect through relative attention to differ with opportunity cost salience (that is, we allow for the coefficient on relative attention to interact with condition).

Consistent with the between-subjects analysis, we find a similar within-subject indirect effect through relative attention. More importantly, we observe a significant moderated indirect effect (\( b = -0.003, 95\% \text{CI based on 5,000 bootstrapped samples:} [-0.007, -0.0002] \)), indicating that the negative indirect effect due to relative attention was stronger in the explicit condition than the implicit condition. Not only do consumers pay more attention to the “keep” option than the “do not buy” option (relative to the “buy” options), but the attention that they do pay is weighted more heavily in the explicit condition than the implicit condition.

Overall, we provide substantial evidence for the role of attention in opportunity cost considerations. In particular, we demonstrate that purchase choices and attention are strongly linked. Subjects devote more relative dwell time to “keep” than they do to “do not buy” — despite the fact that these two options have identical outcomes. In addition to spending more time on the explicit option, the marginal impact of their attention is also greater when they are looking at “keep” compared to “do not buy.” Together, these two factors (amount and impact of attention) help to explain the difference in purchase rates observed between situations with implicit vs. explicit opportunity costs. This work has important implications for decision framing, especially in situations where opportunity costs might be visible and/or attention-grabbing.

**When $5 is Not $5: Search Strategies and Relative Thinking about Money**

**EXTENDED ABSTRACT**

What predicts consumer choices of a $500 television that is more energy-efficient, providing 30 months of usage for a fixed electrical cost, over a $300 television that is less energy-efficient, providing 20 months of usage? Consumer often make choices that involve a trade-off between purchase price (e.g., upfront cost) and operating benefits (e.g., long-term benefits in saving operating costs). In this research, we examine the role of the numeric magnitude of product prices and how information search strategies influence magnitude effects on choice. Research in time preference has shown that people make more patient choices with larger dollar amounts than with smaller ones. For example, Thaler (1981) reported that subjects who were indifferent between receiving $15 immediately and $60 in a year, were also indifferent between $3000 now and $4000 in a year. Generally, the impact of money amount differences on choice tend to be attenuated with larger money magnitudes than smaller magnitudes. For example, consumers are willing to work harder to save $5 on a $15 calculator, but not on a $125 calculator (Tversky & Kahneman 1981).

A potential moderator of this effect in real-world consumer choices is search strategy—how and in what order people acquire information, not just the amount of information. Indeed, previous research (Reeck, Wall, & Johnson 2017) demonstrated that a type of search strategy that facilitates the comparison of attributes across the two alternatives is correlated with greater susceptibility to contextual influences on intertemporal choice. Based on the past research, the present research pursues two aims. First, it examines whether consumers are more likely to choose the more expensive, yet greater operating-benefits option as numeric magnitude of prices increases, controlling for the absolute difference in price (“magnitude effect”). Second, it examines whether those who search in a manner that facilitates the comparison of money amounts (“money-comparative search”) are more susceptible to the magnitude effect. The comparative searching tendency might enhance the identification of the money amount magnitude on which the decision is being made, which would lead to greater susceptibility to magnitude effects.

In Study 1 \( (N = 223) \), participants completed a hypothetical product choice task in which they selected between the more expensive, greater operating-benefits option (e.g., $500 television that provides 30 months of usage for a fixed electrical cost) and the less expensive, smaller operating-benefits option (e.g., $300 television that provides 20 months of usage). They made choices on MouseLabWeb, which provides similar process tracing metrics to eye-tracking. They completed such trials for three products (battery, space heater, and television) and for three levels of absolute price gap between the two options.

Importantly, within each level of absolute price gap, each trial featured the same (jittered) values for operating benefits, so the only difference induced by the manipulation was whether a certain price gap (e.g., $14) was presented with small price magnitudes ($30.8 vs. $44.8), medium magnitudes ($61.6 vs. $75.6), or large magnitudes ($92.4 vs. $106.4). However, consumers chose as if they treated the price gap differently depending on the magnitude it was presented. A generalized linear mixed-effects model with participant random effects showed a main effect of price magnitude \( (p < .001) \). Specifically, the predicted choice proportion of the more expensive, yet greater operating-benefits option was 91% with large magnitudes, 85% with medium magnitudes, followed by 65% with small magnitudes.

To examine the type of search strategy that is more susceptible to this contextual influence, we analyzed the mouse-movements data. Money-Comparative-Search Index was computed as a continuous measure of tendency to compare price between options by acquiring price information across alternatives, as opposed to other types of information acquisitions (i.e., acquisition within each alternative or acquisition of operating benefits information across alternatives). Money-Comparative-Search Index was entered as a regressor along with an indicator for magnitude in a model of choice. Critically, there was a significant interaction between Money-Comparative-Search.
Index and magnitude ($p = .039$). Subsequent analyses revealed a substantial magnitude effect for participants who exhibited high (+1 SD) price-comparative searching (Small = 56%; Medium = 77%; Large = 86%), while the magnitude effect was much less pronounced for those who exhibited low (-1 SD) price-comparative searching (Small = 73%; Medium = 91%; Large = 95%).

Study 2 (N = 267) explored whether the moderating role of search strategy in magnitude effect extends beyond the context in which consumers decide on spending money (money as a loss) to a context in which consumers decide on gaining money (money as a gain). Participants completed an incentive-compatible intertemporal choice task in which they selected between a smaller amount of money delivered sooner and a larger amount of money delivered later. Trials were equally likely to feature small, medium, or large amounts of money for the larger, later option. A continuous measure of comparative search tendency (comparing attributes between options by acquiring information across alternatives) was entered as a regressor along with an indicator for magnitude in a model of patient choice. This analysis revealed a main effect of magnitude on patient choice ($p < .001$), as participants were more likely to select the larger, later option for medium ($\beta = 0.07$, s.e. = 0.01) or large ($\beta = 0.10$, s.e. = 0.01) magnitude trials compared to small magnitude trials. Critically, there was a marginally significant interaction between comparative search tendency and magnitude ($p = .073$): a substantial magnitude effect was found for participants who exhibited more comparative searching, while the magnitude effect was much less pronounced for those who exhibited less comparative searching.

Overall, these two studies reveal that people who tend to compare attributes across alternatives are more susceptible to the magnitude effect. This moderating role of search strategy is confirmed in consumer product choices and intertemporal choices. This work advances our theoretical understanding of information search behavior by suggesting that the tendency to consider relative differences is linked to comparative search. This work also has important implications for choice architecture by implying that information environments that facilitate attribute comparisons across alternatives would make consumers fall prey of the contextual influences more.

**Source, Form, and Form of the Source: A Malleable Monopoly Money Phenomena**

**EXTENDED ABSTRACT**

This paper bridges the literatures on the effects of the “form of money” and the “source of money” on subjective valuations of money. Seven studies show that the subjective value of money is a function of not only its current form, but also a function of its prior form. Said differently, the form of money has a second-order effect and percolates through to other forms it is converted into. Accordingly, gift cards are spent differently as a function of whether they are purchased using cash, credit cards, airline miles or loyalty points (a second order monopoly money effect, Studies 1, 3 and 4; Raghubir and Srivastava 2008), smaller or larger denominations (a second order denomination effect, Study 2; Raghubir and Srivastava 2009). Even legal tender ($100) is valued differently with higher spending and purchase intentions when it is converted from a foreign currency (a second order face value effect, Studies 5a, 5b and 5c; Raghubir and Srivastava 2002).

Study 1, a field study (n=184 from a University paid pool), endowed participants $5 to spend or keep in one of four forms: cash, gift card (GC), points convertible to cash, and points convertible to a GC that could be converted to cash. Participants spent $2.02 on average after exchanging a 500-point gift certificate for a $5 gift card (the “malleable monopoly money” condition) versus $1.18 when they exchanged a 500-point certificate for $5 in cash (F(1, 88)=4.23, p<.05, $\eta^2=0.046$), a difference of 71.19%. The average spend in the two control conditions was no different ($5 cash=$1.69; $5 gift card=$1.65), and was directionally lower than the amount spent in the malleable monopoly money condition.

Study 2 (usable n=122) shows that a $100 gift card purchased using five $20s versus $100 bill is associated with approximately 12% higher spending levels ($M=s67.90 vs. $60.40 respectively, F(1, 116)=3.23, p=.075, $\eta^2=0.027$. This suggests that the denomination effect can carry over to a second-order effect.

Study 3 (n=100 mTurkers) were asked to rate “second order” money forms: gift card purchased with cash, gift card purchased with reward points, and credit card cash back, along with their components: plastic or email gift cards, cash, or reward points, on a $0=Not at all/100=the same as “money” scale. Gift cards purchased with cash ($M=65.15$) were perceived to be significantly more like money than gift cards purchased with reward points ($M=57.64$, t=3.44, p<.05), or email gift cards ($M=58.81$, t=3.29, p<.05), and marginally more so than a plastic gift card ($M=61.97$, t=1.68, p=.10; F(3, 285)=5.50, p=.001, $\eta^2=.055$). In turn, gift cards purchased with reward points were judged to be significantly more like money than reward points ($M=57.64$ vs. 46.43, t=5.16, p<.05) but significantly less like money than credit card cash back ($M=69.48$, t=4.18, p<.05; F(2, 198)=39.61, p<.001, $\eta^2=.286$).

A regression with the subjective value of a gift card purchased with reward points as the dependent variable and the subjective value of an email gift card and reward points as predictors was significant ($F(2, 96)=100.41, p<.001$, $R^2=.67$), as were both coefficients (Standardized $\beta=.54$ and .36 for email gift card and reward points respectively, t=7.23 and 4.79, ps<.001). A similar regression on the subjective value of a gift card purchased with cash with the subjective value of an email gift card and cash as predictors was also significant ($F(2, 94)=76.39, p<.001$, $R^2=.61$), with both coefficients significant (Standardized $\beta=.74$ and .15 for email gift card and cash respectively, t=11.41 and 2.35, ps<.05).

Study 4 (n=162 undergraduates) used a one-way four level design. Participants were asked to imagine that they had gone to a holiday party and brought a gift of $50 in one of four forms: cash, a gift certificate purchased with cash, a gift certificate purchased with credit card points, and a gift certificate purchased with airline miles. Ironically, the participant returned with the same gift that they brought to the party (an elaborate guise to theoretically test the idea that form of the source affects spending), and estimated how much they would spend in a subsequent shopping task. Participants then rated cash, credit card, gift card (GC) paid for with cash, GC paid for with credit card points, GC paid for with airline miles, credit card points, and airline miles on a set of seven-point scales (1=Not acceptable, legal tender, familiar, and how salient the form of the source affects spending), and estimated how much of the GC-cash was significantly different from the GC-points and GC-miles for all scales (all t>5.00, ps<.05).

Regression analyses on the scales replicate Study 3 results.

Finally, studies 5a, 5b, and 5c (n=522 mTurkers, 182 undergraduates, 301 mTurkers) demonstrate that these effects also hold for legal tender: when an unexpected windfall of $100 is received, it
is valued less when it is converted from a foreign currency (versus US$).

Overall, across studies, we show a second-order effect of form, and that the form of a source of money has a sticky effect that percolates to its new form. This effect of the form of the source is termed the Malleable Monopoly Money phenomena. This paper adds to the literature on the effects of the source of money by showing one other facet of source beyond whether it is current or future income/ asset (Shefrin and Thaler 1988), and whether it is a windfall or not (Arkes et al. 1994): its physical form. It adds to the literature on the effect of the forms of money by showing that the physical form of money (credit card, gift certificate, foreign currency, cash denominations) can have a second-order effect. It also adds to the literature on the effects of forms of money by investigating new currencies that are commonly held by consumers: loyalty points and miles.

Beliefs about Future Wealth Impact Investment Decisions

EXTENDED ABSTRACT

When consumers make financial decisions, they need not only think about their current financial situation, but also how their situation might change in the future. The present work investigates how people think about future wealth and how these beliefs impact investment decisions.

Participants (N = 199) in Study 1 saw current asset and debt levels for 20 hypothetical financial profiles and estimated what these asset and debt levels would be in one year. For a random half of participants, the net worth of the profiles was positive and for half it was negative. The value of assets and debts varied across profiles from small (e.g., assets = $67,000, debt = $1,000 in the positive set) to large (e.g., assets = $257,000, debt = $191,000 in the positive set), with the net worth held constant for all profiles in a set. Participants were generally optimistic about the future, predicting that assets would grow over the course of one year while debts would shrink (Zs > |6|; ps < .001). This pattern held for both individuals with positive and negative net worth.

To examine whether predictions were consistent with real world outcomes, we examined changes in individuals’ assets and debts from 2013 to 2015 using data from the Panel Study of Income Dynamics (PSID). During this two-year period, 54% of individuals with positive net worth and 58% of individuals with negative net increased their assets, and 59% of individuals with positive net worth and 66% of individuals with negative net worth decreased their debts. While the majority of individuals in the PSID data followed the general patterns predicted by participants, there are many individuals in this data set who show the opposite pattern, where assets shrink and debts grow. Predictions of participants in Study 1 were generally optimistic and did not reflect the mixed reality demonstrated in the PSID.

Studies 2 (N = 196) and 3 (N = 196) examined whether and how beliefs about future wealth impact investment decisions. In these studies, participants completed two tasks (randomly ordered): a prediction task similar to Study 1 except from a first person perspective and a choice task involving decisions about savings accounts. On each trial in the choice task, participants were given a financial profile (the same set of profiles as in the prediction task) and told that they could invest half of their assets in either a traditional savings account offering 2% interest or a prize-linked savings account offering no interest, but a 1/125 chance of winning a large amount of money in one year (equivalent in expected value to the 2% interest). Study 2 used the same financial profiles as in Study 1. Study 3 used a new set of financial profiles where the value of assets was fixed at either a small or large value (varied between participants) and the net worth ranged from negative to positive.

The pattern of predictions in both Studies 2 and 3 were similar to those in Study 1. Participants generally predicted that assets would grow and debts would shrink. Across the choice task in both studies, participants favored the traditional savings account and selected the prize-linked savings account more often when assets were small as compared to large. In Study 2, the choice proportion for the prize-linked savings account was 0.36 for positive and 0.39 for negative net worth profiles. A generalized linear mixed-effects (GLME) model with by-item random effects showed a main effect of asset value (p < .001) and an interaction between asset value and net worth (p = .022). In Study 3, the choice proportion for the prize-linked savings account was 0.36 for small asset profiles and 0.24 for large asset profiles. GLME results showed a main effect of asset value (p < .001).

Using Hierarchical Bayesian methods, we fit the choice data in Studies 2 and 3 using three different variants of Cumulative Prospect Theory (CPT; Tversky & Kahneman, 1992) arising from different ways of specifying the reference point. In the first version, the reference point was neutral (i.e., set to zero). In the second version, the reference point was determined from the results of the prediction task. For each trial in the choice task, we calculated the predicted growth rate for the assets on that trial using the results of the prediction task. Specifically, growth rate is defined as gr = (Future Value – Present Value)/ Present Value where ‘Future Value’ are participants’ predictions. Using these growth rates, we set the reference point to be the growth rate multiplied by the investment amount on each trial. Since participants generally believe that assets will grow, these reference points are positive and represent an optimistic outlook for the future. In the third version of CPT, we used the same reference points as the second version, but flipped the sign (i.e., -1 times the reference points calculated using the future prediction task). This model assumes a pessimistic view of the future where assets shrink rather than grow. Model comparisons strongly favored the second version of CPT with the reference point determined from the prediction data. The other two versions of the model underpredicted choices of the prize-linked savings account. In particular, the model with the pessimistic reference point (version three), predicted almost no choices of the prize-linked savings account. These findings suggest that people’s optimistic views for the future serve as reference points and encourage risk-taking behavior (e.g., by making the small amount of interest earned in the traditional savings account look like a loss).

In sum, we show the people generally have a positive outlook on the future, believing assets will grow and debts will shrink. While this belief is consistent with reality for many individuals, it does not reflect the more general nature of how people’s financial situations might change in the future. Using computational modeling, we show that these optimistic views of the future serve as reference points when making investment decisions. In particular, we found optimism increased choices for riskier savings accounts (i.e., prize-linked accounts) over traditional savings accounts.

Happens When Others Dislike the Recommendation

Paper #4: The Impact of Feedback on Recommendations: What Happens When Others Dislike the Recommendation

Virginia Weber, Deakin University, Australia
Jennifer Argo, University of Alberta, Canada
Sarah Moore, University of Alberta, Canada

SESSION OVERVIEW

Consumers are living in an increasingly connected world. Social others are constantly present, whether interactions are face-to-face or virtual. Given the profound influence of social contexts on consumption behavior (e.g., Dahl, Manchanda, and Argo 2001; Huang 2018; Ratner and Hamilton 2015; Tu and Fishbach 2015; White and Argo 2014; Wu, Moore, and Fitzsimons 2018), this symposium aims to shed further light. We examine both (1) the impact of others’ mere physical presence (Papers 1-2) and (2) the impact physically and virtually present others who provide information (Papers 3-4), and demonstrate downstream consequences including consumer misbehavior (Paper 1), person perception (Paper 2), consumption decisions (Paper 3) and motivation to make product recommendations (Paper 4).

The first two papers examine the impact of the presence of others in a face-to-face context. Song, Tu, and Huang (Paper 1) show that the crowdedness level in an environment exerts a curvilinear impact on consumer misbehavior (e.g., getting soda without paying at a self-serve beverage station); the odds of misbehaving first increases and then decreases with the increase of crowdedness. They further propose that a shift of crowd construal (perceiving others as individuals or a single entity) underlies this effect.

Schlosser and Hamilton (Paper 2) show that person perception can be moderated by the presence of others. They find that when a target person is alone, using a technology product associated with affiliation, such as a smartphone, leads observers to perceive the target as more socially connected than a person who uses a technology product not associated with affiliation, such as a laptop. However, this effect reverses when the target person is part of a small group.

The next two papers explore the impact of both virtual and physical presence of others who provide information. Allard, Dunn, and White (Paper 3) ask whether negative reviews always hurt and identify fairness as a critical moderator. They find that consumers actually exhibit more favorable responses (e.g., increased patronage intentions and actual purchases) toward a business that received underserved negative reviews from others, because they feel empathetic and wish to restore fairness.

Weber, Argo and Moore (Paper 4) examine how feedback from virtual others influences subsequent motivation to recommend experiences. They show that when consumers make an other-focused recommendation, negative (versus positive) feedback decreases the likelihood of continuing to recommend that experience; on the contrary, when consumers make a self-focused recommendation, consumers continue recommending the same experience, because self-focus can act as a protective shield against the threat from negative feedback.

Collectively, these papers (reporting 19 studies) document the impact of social presence on consumer behavior both offline and online. The findings also offer practical insights on how managers can reduce consumer misbehavior (Paper 1), modify consumers’ reactions to negative reviews (Paper 3), and sustain consumers’ motivation to recommend experiences (Paper 4), as well as how consumers can avoid making negative impressions on others (Paper 2). We believe this symposium will attract a wide audience of researchers interested in social influence, word of mouth, and impression management.

The Curvilinear Impact of Crowdedness on Consumer Misbehavior

EXTENDED ABSTRACT

Consumer misbehavior (e.g., “forgetting” to scan a candy bar at a self-checkout counter, getting soda without paying for it at a self-serve beverage station) is prevalent and costly for companies. While single misbehavior appears trivial, the consequence is huge at a collective level. One critical constraint of this problem is that explicit monitoring from employees is usually weak, and the main source of guardianship actually comes from the presence of other customers. The number of other customers (i.e., crowdedness in the environment), however, can vary significantly across the time of the day. Hence, a question of both theoretical and practical importance is whether and how different levels of crowdedness can influence consumer misbehavior.

We propose that the impact of crowdedness on consumer misbehavior follows a curvilinear pattern; the odds of misbehaving will increase when the level of crowdedness increases from low to moderate, and then decrease when the level of crowdedness increases from moderate to high. We further propose a parsimonious cognitive account for this curvilinear pattern—a shift of crowd construal in evaluating other’s attention. Specifically, when the level of crowdedness is low, people construe others around them as distinct individuals and ask “how many individuals” might pay attention to them (i.e., absolute thinking). As a result, people perceive greater attention when the number of other customers increases, which lowers their odds of misbehaving. However, when the level of crowdedness is high, people begin to construe others as a group (i.e., proportional thinking). As a result, people perceive greater attention when the number of other customers increases, which lowers their odds of misbehaving. However, when the level of crowdedness is high, people begin to construe others as a group (i.e., proportional thinking).
crowd size continues to get larger (e.g., only 5-10 people nearby can notice the misbehavior, as crowd size continues to increase from 30 to 100), people perceive less attention when the environment is more crowded, which increases their odds of misbehaving.

We first conducted an observational study in a fast food restaurant (Study 1). We recorded whether a customer stole soda (i.e., got a water cup for free yet filled it with soda) or not at a self-serve soda fountain. We counted the number of customers in the restaurant every 5 minutes, and used it as a proxy for crowdedness. In support of our hypothesis, we found a quadratic effect of crowdedness on odds of stealing soda ($\beta = .001, \text{Wald} = 4.21, p < .05$). Specifically, people stole soda less when the level of crowdedness was moderate ($M_{\text{moderate}} = 8.4\%$) than when the level of crowdedness was low and high ($M_{\text{low}} = 14.5\%, M_{\text{high}} = 14.8\%; \beta = .21, \text{Wald} = 3.91, p < .05$).

We next replicated the curvilinear effect in a controlled lab setting, using a different type of misbehavior (Study 2). We immersed participants in a 360-degree Virtual Reality video about a park that varied in crowdedness (low, moderate, high) and asked them to step 480 times on a stepper for 8 minutes. We emphasized to them that it was very important that they follow the instruction “to help science,” and used the number of steps as a misbehavior (i.e., cheating in the research study). In support of our hypothesis, we found a quadratic effect of crowdedness on odds of stealing soda ($t(154) = -4.06, p < .001$). Specifically, participants cheated less when the level of crowdedness was moderate ($M_{\text{moderate}} = 2.68, SD_{\text{moderate}} = 88.45\%$) than when the level of crowdedness was low and high ($M_{\text{low}} = 83.67, SD_{\text{low}} = 118.13; M_{\text{high}} = 60.68, SD_{\text{high}} = 96.41; p < .05$).

Having demonstrated the main effect using real misbehaviors and in both a real and controlled setting, we next directly measured the proposed mediator (perceived attention) and linked it to the odds of misbehaving. Study 3 used a 3 (crowdedness: low vs. moderate vs. high) within-participants design. We asked participants to imagine themselves at a food court with other customers, and provided them with a visual aid in which we used human silhouettes (1, 10, and 100 silhouette; randomized order) to represent others, a common method used in crowding research (O’Guinn et al. 2015; Huang, Huang, Zhong, and Wyer 2018). Participants then imagined that they were standing in front of a self-serve soda fountain and felt tempted to fill their water cup with soda. Participants rated to what extent others may notice them and their likelihood to steal soda. In support of our hypothesis, in the moderately crowded condition participants reported perceiving greatest attention ($M_{\text{moderate}} = 3.67$) than the other two conditions ($M_{\text{low}} = 3.17, M_{\text{high}} = 3.41; F(1,115) = 5.38, p < .03$), as well as the lowest intention to steal soda ($M_{\text{moderate}} = 2.66$) than the other two conditions as well ($M_{\text{low}} = 2.78, M_{\text{high}} = 2.91; F(1,115) = 3.24, p = .075$).

Study 4 investigated our proposed cognitive mechanism, a shift of crowd construal and, subsequently, a reliance on absolute to proportional thinking in estimating attention. This study used a 5 (crowd size: 1, 4, 10, 30, vs. 100 human silhouette(s)) between-participants design. Participants imagined a similar scenario as in study 3, reported how their perception of the crowd (distinct individuals or a single entity), perceived attention, the absolute number of people who may notice them (i.e., absolute thinking), and the proportional of people who may notice them (i.e., proportional thinking). We find that participants were more likely to perceive the crowd as a single entity when the crowd size increases ($F(4, 195) = 8.73, p < .001$) and replicated the curvilinear pattern for perceived attention ($F(1, 195) = 4.09, p < .05$). More importantly, supporting our proposed mechanism, absolute thinking mediated the effect of crowdedness on perceived attention when the level of crowdedness increases from low to moderate ($\beta = -.12, 95\% \text{CI } [-.28, -.04]$), whereas proportional thinking mediated the effect of crowdedness on perceived attention only when the level of crowdedness increases from moderate to high ($\beta = -.07, 95\% \text{CI } [-.18, -.00]$).

Taken together, we document the impact of the whole spectrum of crowdedness on consumer misbehavior, as well as offer a parsimonious cognitive account for the identified curvilinear pattern. Our findings offer insights on how marketers can leverage the power of informal social monitoring for managing stores more cost-effectively.

**Graded and Context-Dependent Technology Associations: Why Using a Smartphone Can Signal Both More and Less Social Connection**

**EXTENDED ABSTRACT**

Consumers are often observed by others as they use technology products such as smartphones and laptops. Despite the similar functions performed by a smartphone and a laptop, such as sending and receiving emails, managing one’s calendar, or searching for information, their perceived affordances differ. Perceived affordances depend on what observers think the technology user is doing or trying to accomplish, and which needs are being fulfilled by using the technology (Norman 1999). For example, smartphones, which are often used to communicate with others, tend to be associated with affiliation needs, leading to inferences about social connection (e.g., how popular and well-liked a person is). In contrast, laptops, which are often used to work and access information (Schlosser 2003), tend to be associated with achievement needs, leading to inferences about busyness.

Theories of person perception suggest that observers form impressions of others based on their actions (Kammrath Mendoza-Denton and Mischel 2005; Kelley 1972) and that the associations of products transfer to their users (Escalas and Bettman 2005). Once these technology associations have been established, the mere presence of a technology can cue these associations (Schlosser 2003). We extend this research by investigating how technology associations differentially affect perceptions of users based on a) their level of interaction with the technology and b) the social context in which the technology is used. Akin to graded category membership (Rosch 1975), we propose that greater interaction with a technology will increase the technology association, and thus, the degree to which observers infer that a user inherits a technology’s associations (H1). Turning to social context, because smartphones are associated with affiliation, we find that their usage competes with the demands of affiliating with others in a small group. Consequently, using a smartphone reduces perceived social connection when the user is in a small group, but not when alone (H2-H3). In contrast, using a functionally similar technology (a laptop) in a small group does not reduce perceived social connection because it triggers different associations (achievement). Such a prediction extends recent research showing that using the same product may create different impressions depending on whether its use is normative or counter-normative in the setting (Bellezza, Gino and Keinan 2014) by linking this reversal to product-specific usage associations. By demonstrating that perceptions of technology users depend on both technology-specific associations and the social context, we provide new insights into person perception.

We test our predictions across a pilot study and five experimental studies. In the pilot study, we show that despite the similar actual affordances of smartphones and laptops, these two technology products differ in their perceived affordances: smartphones are associated more with affiliation, while laptops are associated more...
with achievement. In our first study, we show that technology associations depend on the user’s level of interaction with the technology (H1: graded product associations). Furthermore, we show that level of technology interaction affects observers’ inferences about social connection, and thus, being in demand by employers, and these inferences are moderated by the social context (H2-H3). In our second study, we replicate our finding that different types of technology (e.g., laptops vs. smartphones) have different associations. As a result, using a smartphone and using a laptop cause observers to draw different inferences about the social connection of their users. In our third and fourth studies, we show that technology associations differ for users and non-users of the technology and that observers’ inferences differ for users and non-users. Furthermore, changing the observer’s beliefs about how the technology is being used moderates the effect (H4). For example, in studies 4 and 5, we find that when a smartphone is being used in a non-competitive rather than competitive manner (i.e., to affiliate with the face-to-face group rather than affiliate with a virtual other), the perceived social connection of someone using a smartphone in a group is comparable to that of someone not using a smartphone in a group. Furthermore, in our last study, we observe these effects even when the group norm supports smartphone usage (i.e., everyone in the group is using a smartphone).

Clearly, the ubiquity of multifunctional technology products like smartphones and laptops introduce new challenges for consumers trying to interpret others’ behavior and manage others’ impressions of themselves. By examining observers’ perceptions of technology use, we are able to push the boundaries of person-perception research by showing that different inferences may be made about the same person using the same technology in the same public setting depending on how intensively they are interacting with the technology and whether they are using the technology in a small group or while alone. To effectively decode others’ behavior and manage others’ perceptions of them, consumers must understand the perceived affordances of the technologies they use, the settings in which these perceived affordances may create negative impressions, and how to interact with the technologies to avoid these negative impressions. As technology has become more complex in the twenty-first century, so has person perception and impression management.

Feeling Bad for the Brand: Encouraging Positive Consumer Reactions to Unfair Negative Reviews through Empathetic Responding

EXTENDED ABSTRACT

Managing negative reviews is an important task for companies. This is because WOM is viewed as being more authentic, relevant, and unbiased than communications that stem from the company itself (Fristad and Wright 1994). Within the WOM literature, negative reviews lead to less favorable firm evaluations, and positive reviews lead to more favorable firm evaluations (e.g., Chevalier and Mayzlin 2006; Fornell and Westbrook 1984). Both types of reviews, negative and positive, greatly influence consumer decision-making (Basuroy, Chatterjee, and Ravid 2003), but negative reviews are often the most impactful (Chen and Lurie 2013; Mizerski 1982).

However, the increasing influx of online reviews has left managers conflicted on how to deal with common public displays of customer disgruntlement, which may or may not accurately reflect the quality of the firm’s products and services (e.g., O’Brien and Hosany 2016). In this research, we examine the reactions of third-party observers to negative reviews of a focal firm that are perceived to be unfair based on the firm’s performance. We draw upon work on empathetic responding in person-to-person contexts (Batson and Ahmad 2001) to argue that when consumers perceive a negative review to be unfair, they experience empathetic concern for the firm being wronged. In turn, these feelings of empathy trigger favorable consumer responses toward the focal firm, such as increased patronage intentions and actual purchases, in order to restore a sense of justice fairness.

Study 1 (n = 75, field sample) offers an initial real-world test of the hypothesis that exposure to unfair WOM can influence an observer’s subsequent response in a meaningful choice context. We operated a pop-up, with all proceeds donated to a local food bank. In both the control and unfair conditions, a confederate stood nearby, acting as another customer. When a customer approached, the confederate addressed the representative by either simply saying, “Thank you,” and walking away without making a purchase (control) or “Is this organic? Why would you serve non-organic products? I’m going to pass,” and then walk away without making a purchase (unfair negative). Participants could then make their iced-tea purchase. Consistent with our key prediction, consumers paid significantly more for the iced tea in the unfair-negative-review condition (M = $2.92, SD = $1.84) compared to those in the control condition (M = $1.91, SD = $1.54; t(73) = 2.34, p = .01).

Study 2 (n = 182 Mturk sample) replicates this effect by comparing the unfair-negative-review condition to both a fair-negative-review condition and a positive-review condition. The reviews included a picture and described enjoyment of a “tasty full-meal breakfast” with coffee, which the reviewer liked, for a total of $12. However, in both negative conditions, the review included an additional negative remark about the price of coffee within the $12 combo. In the fair negative review, the meal and the coffee were priced at $7.50 and $4.50, respectively. In the unfair negative review, these items were priced at $11.50 and $0.50, respectively. Results revealed a significant effect of review type on patronage intentions (F(2, 179) = 10.76, p < .001). Importantly, patronage intentions were higher in the unfair negative (M = 4.80, SD = 1.69) compared to the positive (M = 4.04, SD = 1.97; t(179) = 2.33, p < .05) and the fair negative-review conditions (M = 3.24, SD = 1.67; t(179) = 4.63, p < .001). Patronage intentions were also higher in the positive compared to the fair negative condition (t(179) = 2.48, p = .01). Importantly, mediation analyses revealed that heightened feelings of empathy for the firm in the unfair-negative condition predict the difference in patronage intentions between the unfair negative and the fair negative conditions (b = 1.02, SE = .22; CI95 [.65, 1.54]) and between the unfair negative and the positive conditions (b = .97, SE = .21; CI95 [.62, 1.43]).

Study 3 (n = 205, MTurk sample) tested whether trait empathy moderates the effect of review type on consumer patronage intentions. Using a 3 (review type: unfair negative vs. fair negative vs. positive) X continuous (trait empathy) between-participants design in another review context, results from this study replicated those of study 2 and showed a moderating effect of trait empathy on patronage intentions. Study 4 (n = 320, student sample), replicate these finding in a different online restaurant review context using a low or high-empathy manipulation procedure (Batson and Ahmad 2001).

Study 5 (n = 487; Mturk sample) tests a managerial intervention to enhance empathetic response. We asked participants to read an online review from a consumer who had recently ordered a set of garden tools from a hardware store. Constant across the conditions, the consumer received the tools in good conditions, but noted that the selection was limited. In the positive review, the customer gave a 4-star review and did not provide further information. In the fair-negative-review condition, the customer gave a 1-star review and added a complaint about the firm for shipping delays. In the un-
fair negative-review condition, the customer complained about the postal service (USPS) for shipping delay. The firm then responded in a high-empathy (personalized) or a low-empathy (non-personalized) manner. Importantly, purchase intentions following the unfair negative review with high-empathy responses were not significantly different from the positive review conditions (t’s < 1), whereas these two condition were each significantly different from the unfair negative review condition with a low-empathy response (low-empathy response: t(472) = 2.36, p < .05; high-empathy response: t(472) = 3.16, p < .01). These results demonstrate that utilizing a personalized approach evokes higher empathy for the firm regardless of whether the negative review is perceived to be fair or not.

Taken together, those results support the notion that undeserved negative reviews can draw sympathetic consumer responses due to heightened feelings of empathy toward the firm. Importantly, we show that managers can increase empathetic responses towards their firms by simply changing to more personable responses when dealing with undeserved negative reviews.

The Impact of Feedback on Recommendations: What Happens When Others Dislike the Recommendation

EXTENDED ABSTRACT

Consumers constantly make recommendations to others (e.g., songs to hear, movies to watch). Often, the recipient will follow the recommendation and later tell the recommender what they thought of the experience. What are the implications of this feedback? Currently, the answer is unknown. In this research, we seek to address this void by exploring the impact of feedback valence (i.e., whether the recipient finds the recommended experience positive or negative) and the recommender’s focus (self vs. other) on whether the recommender continues to engage in word of mouth (WOM) for this experience.

In keeping with prior research on feedback (Baumeister et al. 2001; Bloom and Hautaluoma 1987), we predict that after making a recommendation and receiving positive feedback about the experience, recommender will continue spreading WOM about it, whereas negative feedback will result in decreased subsequent WOM. This is because negative feedback will be threatening to consumers (Steele 1988), causing them to distance themselves from the experience they have recommended (Ward and Broniaczyk 2011; White and Argo 2009).

However, this may not always be the case. When the recommender makes an other-focused recommendation (i.e., they take their recipient’s preferences into account when recommending; Barasch and Berger 2014) we expect this effect to hold. This is because another person disliking a recommendation specifically tailored to them constitutes failing, which becomes threatening to the self (Steele 1988) and so causes the recommender to distance themselves from it. In contrast, when recommenders make self-focused recommendations (i.e., they base their recommendation solely on the self), we predict this self-focus acts as a protective shield against the threat from negative feedback. As such, recommenders who are self-focused should not decrease their subsequent WOM after negative feedback.

We test these predictions across five experiments. In each of the experiments, the basic procedure was as follows: participants were paired either ostensibly (online) or in person (lab), sampled experiences (movie trailers or songs) and made a recommendation from these experiences to their partner, after which they received (false) feedback about the degree to which their partner liked the experience, and then reported their subsequent WOM intentions.

Experiment 1a assessed the main effect of feedback (positive vs. negative), following the procedure outlined above and holding the recommender’s focus constant as other-focus (N=206) by telling participants (N=206) to recommend the movie trailer their partner would like the best. Results revealed that participants who received negative feedback were less willing to continue recommending this experience relative to those who received positive feedback (Mneg = 5.16; Mpos = 4.55; t(201), p = .008).

Experiment 1b (N=301) extended these findings to include two control conditions to demonstrate that the effect was not due to positive feedback increasing subsequent WOM relative to neutral feedback or no feedback, for a total of 4 conditions (positive vs. negative vs. neutral vs. no-feedback). Results revealed a main effect of feedback on WOM intentions (F(3, 293) = 3.68, p = .012). Those in the negative feedback condition had lower WOM intentions than those in the neutral (M = 5.19; p = .035), positive (M = 5.36, p = .003), or control (M = 5.13, p = .006) conditions, which did not differ (p ns > .4).

Experiment 2 employed a self-affirmation task (Steele 1988) to provide evidence of threat as the underlying process. This study (N=446) was a 2 (feedback: positive vs. negative) by 3 (affirmation: before vs. after vs. no-affirm control) design. In the affirm-before condition, participants completed a self-affirmation task before receiving feedback; in the affirm-after condition, this occurred after the feedback. In the no-affirm condition, participants did not complete a self-affirmation task. Results revealed a significant interaction (F(2, 435) = 3.01, p = .05). As expected, in the no-affirm condition, participants were less likely to continue recommending after negative feedback (Mneg = 5.84; Mpos = 4.44; p < .0001). In the affirm-after condition, this difference became marginal (Mneg = 5.39; Mpos = 4.99; p = .092), and was attenuated in the affirm-before condition (Mneg = 5.55; Mpos = 4.84; p > .6). As such, only being bolstered against this threat before it occurs is sufficient in fully attenuating its impact.

Experiment 3 aimed to provide evidence for the moderating role of self-focus. This study was run in the lab using a 2 (feedback: positive vs. negative) by 2 (focus: self vs. other) design. Participants (N=103) were told to select the movie trailer they believed their partner would like the best (other-focus), or the one they liked the best (self-focus). Results revealed a significant interaction (F(1, 95) = 4.07, p = .047). When participants made other-focused recommendations, they were less likely to continue recommending the trailer after receiving negative feedback (Mneg = 5.36; Mpos = 3.88; p = .001), whereas when participants were self-focused, this effect was attenuated (Mneg = 5.60; Mpos = 5.15; p > .5).

Experiment 4 (N=94) was also a 2 (feedback: positive vs. negative) by 2 (focus: self vs. other) design. For generalizability and robustness, participants recommended any song of their choosing to their partner. Further, recommendation focus was manipulated by telling participants that their partner had the same music preferences as they did (self-focus) or that they had different preferences (other-focus), as prior literature finds that greater self-other overlap increases egocentrism (i.e., self-focus; Savitsky et al. 2011; Tu, Shaw, and Fishbach 2016). Otherwise the procedure was the same as outlined above. The interaction was significant (F(1, 89) = 9.80, p = .002); other-focused participants were less willing to continue recommending the song (Mneg = 6.32; Mpos = 4.78; p = .001), whereas when participants were self-focused, this effect was attenuated (Mneg = 5.74; Mpos = 6.04; p > .4).

In sum, negative feedback on one’s recommendations can decrease subsequent WOM, but only when a consumer makes a recommendation with their recipient’s preferences in mind. This work contributes to research on WOM by introducing the notion of feedback...
to this literature, and contributes to work on threat by demonstrating that self-focus can provide a protective barrier against threat.

Four papers examine facets of the decision environment that affect consumers’ food choice decisions. Papers 1 and 2 explore how consumers process health information and how retailers can use this information to promote healthier choices. Paper 1 finds that changing the default option (e.g., fries with a hamburger) can shift consumers’ attention and prompt them to make healthier choices. Paper 2 demonstrates that consumers have differing preferences when it comes to restricting their caloric intake. Restrained eaters prefer to eat diet options in larger portions, while unrestrained eaters prefer to eat indulgent options in smaller portions. This suggests that retailers should offer both options (e.g., low-calorie, and small portion) to appeal to distinct consumer segments. Papers 3 and 4 examine how front-of-package (FOP) labels specifically can alter consumer behavior and store profits. Paper 3 tests the efficacy of FOP labels in an online store context. Using newly developed online shopping software, the authors demonstrate that FOP labels can prompt consumers to make healthier food choices when shopping. Paper 4 demonstrates that food retailers who add health labels to their weekly circular increase their weekly sales in advertised product categories. This increased spending is especially pronounced in nutrition conscious consumers. Together, papers 3 and 4 demonstrate that grocery retailers can use labels to improve consumers’ decision making while also improving sales.

In sum, these papers provide insight into how changes in the grocery environment can alter consumers’ choice and the store’s sales. In addition to adding conceptually to the literature on health nudges, these papers use an array of methodological strategies eye tracking, survey research, field studies, and a mock online store which may be of interest to health researchers. This session should have broad appeal to researchers studying health and nutrition, nudges, and consumer decision making.

**Helping Consumers Make Wise Choices About Food**

**SESSION OVERVIEW**

Many consumers have a goal to eat healthy (Snook et al., 2017). When consuming a healthy diet, individuals are simultaneously lowering their risk of nutrition-related illnesses (WHO, 2002) and increasing their energy levels and cognitive performance throughout the day (O’Connor, 2006). Despite these benefits, consumers often overeat and fail to meet their nutrition goals. Although overeating is often conceptualized as a failure of willpower, a consumer’s environment also plays a large role in whether he or she overconsumes (Loewenstein, 2000).

A growing literature on nudges demonstrates that small changes to choice environments can impact how consumers behave (Thaler & Sunstein, 2009). The purpose of this session is to examine ways in which retailers can modify the decision environment to simultaneously improve consumer food-related decision making and grow the retailer’s profit.

**Extended Abstract**

**Introduction**

Consumers often have at least two competing goals when making dietary choices: the desire for tasty foods and the desire to be at a healthy weight. The difficulty in achieving both goals simultaneously is evidenced by continued rises in obesity rates, despite surveys suggesting that 50% or more of obese Americans are actively dieting at any time (Snook et al., 2017). Individual obesity has been linked to a prominent feature of the choice environment: the prevalence of unhealthy foods (Burgoine, Forouhi, Griffin, Wareham, & Monsivais, 2014; Swinburn, Egger, & Raza, 1999). For example, french fries, not carrots, are the default accompaniment at nearly all fast food restaurants. Although unhealthy defaults are likely to contribute to the obesogenic environment, they also present an opportunity to improve choices by switching them for healthier options. An improved understanding of how default options shape dietary choices could identify approaches for changing choice architecture, and thus improving choices without needing to alter consumers’ underlying preferences (Johnson et al., 2012).

In addition to their designation as the default, defaults can influence choices through at least three distinct pathways. First, moving away from the default is often effortful, requiring additional physical actions, mental processing, or interaction (Dinner et al., 2011). Second, consumers may lack awareness of alternative options, especially in complex retail environments. Third, customers often have greater familiarity with the default option. Field and lab experimental defaults often feature at least one of these additional advantages, preventing a thorough understanding of the influence of default status alone. To isolate the influence of the default status itself on healthy choice, we designed a task in which both the default and alternative options were equally familiar, and 3) participants were equally aware of both options.

**Methods**

Across two experiments, participants made choices about pairs of common snack foods that varied in their healthfulness and tastiness. Across a total of 300 trials, we varied whether there was a tastier but less healthy default option (“Indulgent default”), a healthier but less tasty default option (“Disciplined default”), or no default at all.
Results.

In both experiments, participants selected the default more than the alternative (Study 1, mean = 54%, t(50) = 7.61, p < 0.001; Study 2, mean = 54%, t(38) = 5.48, p < 0.001). This resulted in choices that were healthier in the Disciplined default condition, both compared to the Indulgent default condition, and the Baseline condition (p < 0.001). The default received significantly more attention than the default across both experiments (Study 1 mean difference = mean = 7%, t(50) = 10.64, p < 0.001; Study 2 mean difference = 8%, t(38) = 8.59, p < 0.001). Drift diffusion modeling suggests that the weight placed on the default’s reported wanting during option comparison was greater than that of the alternative option, suggesting that the status of the default gives that food a “value boost.” Further, there was an initial bias toward the default at each trial’s outset, giving the default a “head start” in option comparison. Using regression analysis, we estimate the relative influence of each of these advantages on choice, and find that the additional proportion of gaze to the default is the largest driver of the default bias. Despite this, the “value boost” given to the default option remains a significant driver of choice, suggesting that the default designation imparts some significant value enhancement to the option that promotes its selection.

Conclusion.

In two independent experiments, we tested the power of default options to bias choice while holding many common features of them such as the ease of choosing them constant across both the default and alternative option. Despite this, we still find a significant bias toward choosing the default even when it is healthier and less tasty than the alternative. Using both eye tracking and modeling, we pinpoint the ways in which default status influence the decision process, such as the additional attention devoted to it. These results suggest several promising interventions. For example, menu presentation that increases gaze time to healthier options, such as with highlighting or order of presentation, may be promising avenues for future interventions. However, gaze bias does not explain away the default effect; the default receives an additional “value boost” that influences choice even when controlling for attentional effects. This suggests that simply substituting unhealthy defaults like french fries and soda for healthier options could have a profound influence on consumer choice.

Sacrifices Must be Made: The Preference for Trading Off Type or Quantity Among Restrained Versus Unrestrained Eaters

EXTENDED ABSTRACT

Ideally, consumers would prefer to eat tasty, enjoyable foods in desired quantities without health consequences. However, goals to lose or manage weight can necessitate caloric intake sacrifices. We conceptualize two fundamentally different sacrifice forms: sacrificing the type(s) of food or the quantities consumed. Although food marketers cater to both kinds of sacrifice, and much research examines each kind of sacrifice separately, relatively little is known about how these two kinds of sacrifice differ. We present five studies examining perceptions of and preferences for sacrificing type versus quantity (holding caloric change constant), considering the moderating role of dietary restraint. We examine dietary restraint, as it is an important eating individual difference that may shape many consumer psychological phenomena (Bublitz, Peracchio, & Block, 2010).

This research thus offers a novel perspective on how two main sacrifice routes that entail the same caloric decrease are differentially perceived, and for understanding preferences and goal-based differences between restrained and unrestrained eaters. This is important because marketplace offerings address each sacrifice route and food type and quantity are of theoretical interest yet typically examined separately despite being joint inputs to total intake.

Studies 1-3 test our prediction (drawing from theorizing about goals, as detailed in Studies 4-5) that dietary restraint will predict preferring to sacrifice type over quantity, such that restrained eaters will prefer sacrificing type, whereas unrestrained eaters will prefer sacrificing quantity.

Study 1 (N=178) tested this prediction using real snack choices. Participants were told that a company traditionally selling medium-sized buttered popcorn bags (200 calories) was planning to add two new popcorn options: one new bag was “the same size but 94% fat-free and thus half the calories” (sacrificing type) and the other was “half the size and thus half the calories” (sacrificing quantity). Participants chose a snack bag and completed three measures of dietary restraint: a 9-item scale from Stice (1998), a 10-item scale from Herman and Polivy (1980), and a one-item chronic dieting measure. Fifty percent of participants selected each snack bag, and all three measures of dietary restraint predicted choosing to sacrifice type versus quantity (all ps < .05).

Study 2 (N=154) generalized these findings to eight stimuli sets involving various snacks, entrees, condiments, and desserts, and tested the unique role of dietary restraint amongst other eating-relevant individual differences. For instance, participants were asked which they would switch to, from a snack of a medium bag of BBQ potato chips (250 calories) (1=Definitely a small bag of BBQ potato chips (125 calories), 4=Equal preference for each option, 7=Definitely a medium bag of light BBQ potato chips (125 calories)). Participants’ responses to the eight stimuli sets were averaged to form one preference index (1=sacrificing quantity, 4=equal preference, 7=sacrificing type (α=.82). Participants also completed a dietary restraint scale and additional individual differences (e.g., eating self-control, gender, BMI). As predicted, dietary restraint predicted preferences to sacrifice type versus quantity (r=.31, p<.001); no other eating-relevant individual differences did.

Study 3 (N=210) tested this prediction in a marketing context in which participants responded to ads advertising either a sacrificing via type product or a sacrificing via quantity product, instead of having both options pitted against each other. Using a 2 (advertisement: sacrificing type, sacrificing quantity)×dietary restraint be-
 tween-subjects design, participants evaluated an advertisement from a company traditionally selling medium-sized buttered popcorn (400 calories). Participants read that the company planned to add a new option and viewed an ad either for a product with “the same size but 94% fat-free and thus half the calories” (sacrificing type condition) or “half the size and thus half the calories” (sacrificing quantity). Participants indicated their purchase intentions and completed a dietary restraint scale. Analysis revealed a significant interaction ($B$=.68, $SE$=.29, $t=2.38$, $p=.018$), such that unrestrained eaters had higher purchase intentions for the advertised product when it promoted sacrificing quantity (vs. type), whereas consumers with restrained eaters showed the opposite. See figure 1.

Studies 4 (N=104) and 5 (N=103) then tested our theorizing—built on integrating literature on food decision-making goals, and how such goals may differ across restrained and unrestrained eaters (Dhar & Simonson, 1999; Liu et al., 2015; Ogden & Wardle, 1990; Raghunathan, Naylor, & Hoyer, 2006). Specifically, we examined whether the two consumer segments have different perceptions of the sacrificing type option to be the healthier option and the sacrificing quantity option to be the more enjoyable option, and whether restrained eaters perceive the sacrificing type option to be the more filling option. Study 5 examines goal priorities, testing whether restrained eaters (relative to unrestrained eaters) prioritize health goals, deprioritize taste goals, and similarly prioritize fullness goals when making a food choice. Study 4 participants indicated which they would switch to if their typical snack of a medium buttered popcorn (400 calories) were unavailable (1=Definitely a small buttered popcorn (200 calories), 7=Definitely a medium 94% fat-free popcorn (200 calories)). They then rated each of these two foods on perceived ability to address taste, health, and fullness goals, before completing a dietary restraint scale. Study 5 had a similar design, except rather than rating perceived ability to address goals, participants indicated the importance of addressing their health, taste, and hunger goals. Collectively, studies 4 and 5 show that the differing sacrificing preferences among restrained and unrestrained eaters occur because of the different weights placed on addressing health versus taste and the different fullness perceptions of the sacrificing quantity versus type options ($p=.05$; figures 2a-2b).

These findings have theoretical implications for understanding two major routes to decreasing caloric intake, consumption and psychological motivational differences between restrained and unrestrained eaters, and health-taste-fullness trade-offs. They have practical implications for consumer welfare and for marketers about which route to health better appeals to various consumer segments. A final sixth study also shows how this perspective extends to examining sacrifices in the monetary spending domain, suggesting that we capture a broader phenomenon wherein those who chronically restrict resources sacrifice on type rather than quantity.

Using a Novel Online Grocery Platform to Explore How Front-of-Package Labelling Affects Consumers’ Food Choice

EXTENDED ABSTRACT

Promoting healthy food choice is critical to reducing nutrition-related chronic illnesses (WHO, 2002). Front-of-package (FOP) health labels may be a useful tool to signal the nutritional value of products to consumers. Some studies have shown that consumers who see FOP labels make healthier choices in (real or experimental) grocery stores (Hobin et al., 2017; Maubach, Hoek, & Mather, 2014; Nikolova & Inman, 2015; Sutherland, Kaely, & Fischer, 2010) except for not labelling 0-star products. The largest supermarket retailer in Canada rolled out the Guiding Stars system in supermarkets across Ontario, Canada. The aim of our study was to examine the extent to which consumers respond to an on-shelf nutrition labelling system in supermarkets to inform current and future nutrition labelling policies and practices. Methods: Capitalizing on a natural experiment, we conducted a quasi-experimental study across 3 supermarket banners (or “chains”). Other studies have found no effect (Aschemann-Witzel et al., 2013; Sacks, Tikellis, Millar, & Swinburn, 2011). Reviews on the topic generally conclude that the evidence for FOP labels is promising, yet inconclusive (Cameron, Charlton, Ngan, & Sacks, 2016; Escaron, Meinen, Nitzke, & Martinez-Donate, 2013) such settings are optimal for interventions aimed at influencing these decisions. The objective of this review was to synthesize the evidence on supermarket and grocery store interventions to promote healthier food choices. METHODS We searched PubMed through July 2012 to identify original research articles evaluating supermarket and grocery store interventions that promoted healthful food choices. We categorized each intervention by type of intervention strategy and extracted and summarized data on each intervention. We developed a scoring system for evaluating each intervention and assigned points for study design, effectiveness, reach, and availability of evidence. We averaged points for each intervention category and compared the strength of the evidence for each category. RESULTS We identified 58 articles and characterized 33 interventions. We found 7 strategies used alone or in combination. The most frequently used strategy was the combination of point-of-purchase and promotion and advertising (15 interventions).

Furthermore, although consumers are increasingly doing their grocery shopping online (Daniels, 2017), there has been no research on how FOP labelling affects consumer choice in online settings. There are several reasons consumers choices online might differ from their choices in brick-and-mortar stores. First, in online environments, retailers can label foods that traditionally remain unlabeled (e.g., produce, deli). Second, non-sensory attributes, like labels, exert a stronger effect on consumers in online (versus brick-and-mortar) environments (Degeratu, Rangaswamy, & Wu, 2000). Third, consumers shopping online (versus in-store) are more motivated by “should’s” than “want’s,” which may lead to a stronger labelling effect (Milkom, Rogers, & Bazerman, 2016).

In three studies, we demonstrate that FOP “Healthy Stars” labels improve consumers’ choices. The Healthy Stars label was developed by the researchers and is based on the Guiding Stars nutritional labelling system. The Healthy Stars label rates foods from 0 (not healthy) to 3 (very healthy) stars. Studies 1 and 2 demonstrate the effect of Healthy Stars in a limited experimental setting. Study 3 expands the findings using an open-source online grocery store.

Study 1

Methods

Participants (N=191) imagined shopping for cereals for themselves. Participants were shown an array of 12 cereals of varying health levels (three of each star level). Depending on condition, the cereals were labelled with Healthy Stars or not. Price and nutrition information were not shown to participants. Participants chose one cereal, and then were asked a series of questions about the chosen cereal, a healthy cereal from the set, and an unhealthy cereal from the set. The questions pertained to perceived healthiness, anticipated tastiness, and anticipated emotions. Results from the questions are not discussed here.
Results and Discussion

Participants who saw Healthy Stars labels chose cereals with a higher star rating on average ($M=1.81$) than participants who did not see healthy stars labels ($M=1.19$), $p<0.01$. However, participants made this decision in the absence of nutritional information. We ran Study 2 to determine if the effects would persist when nutrition labelling was also available for the cereals. In Study 2, we also tested whether FOP labels would be more effective for some consumers over others. Namely, we tested whether BMI, time affluence, education, numeracy, and dietary confidence moderated the effect of labels on choice.

Study 2

Methods

Participants ($N=350$) participated in a 2 (Healthy Stars: displayed, absent) X 2 (nutrition facts label: available, unavailable). Namely, participants saw the same array of 12 cereals used in Study 1. The only change was that some participants were able to click a button below the cereal to see the relevant nutrition information. Participants competed the same measures as Study 1 in addition to BMI, education level, time affluence, numeracy, and dietary confidence.

Results and Discussion

A 2(Stars) X 2(Nutrition Facts) ANOVA on choice revealed a main effect of Stars and no other effects. Participants who saw the Healthy Stars labels chose cereals with a higher star rating on average ($M=2.03$) than participants who did not ($M=1.19$), $p<0.001$. This effect was not moderated by BMI, numeracy, or diet confidence. The effect was stronger for time affluent participants (vs. time poor participants; $p=0.08$) and college educated (vs. not college educated) participants ($p=0.02$).

Study 3

Although promising, our effects have thus far been limited to a small subset of items in a highly controlled experiment. For Study 3, we developed an open-source researcher-controlled online grocery store (www.openscience-onlingrocery.com). The store contains over 10,000 products. Participants use the store like they would use a commercial online grocery store (e.g., peapod, Instacart), except that no transaction takes place. Researchers are able to monitor which products consumers examine, add to cart, and check out with. Researchers can also make modifications to the way products are labelled, categorized, and ordered. For Study 3, we created two versions of the store: one with star labels and one without.

Methods

Participants ($N=156$) were asked to imagine shopping for two days for themselves. After receiving a primer on the store, participants were directed into a version of the store with or without stars. The primary dependent variable is what products participants checked out with.

Results

The average star rating of the foods in participants’ carts was not significantly higher in the stars ($M=1.48$) versus control condition ($M=1.36$). However, controlling for the number of items purchased, people in the Stars condition purchased significantly more three-star items ($M=4.05$) and fewer one-star items ($M=0.46$) than participants in the control condition ($M=3.00$; $M=1.15$), both $p<.01$. Controlling for total number of items purchased, people in the stars condition also bought more products from the Produce category ($M=2.86$) than participants in the control condition ($M=2.36$), $p=.051$, but this did not mediate the effect of labels on number of three-star items purchased.

Conclusion

An increasing number of consumers grocery shop online (Daniels, 2017). While online shopping, consumers may be more receptive to health labels (Degeratu et al., 2000; Milkman et al., 2016). In three studies, we present evidence that consumers make healthier choices when provided with FOP labels in an online context. This occurs regardless of whether nutrition facts labels are presented alongside FOP labels. It is unclear why FOP labels outperform nutrition information. Ongoing research will probe this finding. We also introduce a new tool for studying how consumers behave while shopping online.

How Do Nutrition Promotions Impact Shoppers’ Sensitivity to Price Promotions?

EXTENDED ABSTRACT

Grocerry retailers play a key role in the fight against the obesity epidemic by offering diverse health and wellness programs at the point of sale. Consumers trust food retailers to support their health more than ever before and even evaluate food retailers based on how well they support their goal of eating healthy (FMI, 2018). While prior research has contributed significant insights into the success of such programs in promoting healthy choices among consumers (Nikolova & Inman, 2015; Newman et al., 2018), their impact on retailers’ sales is still not fully understood. This is precisely the objective of our research to examine how consumer reaction to nutritional information in retailer promotions impact sales.

While retailers provide shoppers with simplified nutritional information in a variety of forms (color coding, nutrition scores), we focus on the use of NuVal scores, ranging from 1 to 100 with higher scores signifying healthier products. Prior research has examined how the introduction of the NuVal scoring system impacts shoppers’ purchases (Nikolova & Inman, 2015). In contrast, our research examines consumer responses after the nutrition scoring system has been in place for a while and its novelty has worn off. Specifically, we look at the impact of featuring the NuVal scoring system in the weekly promotion flyers.

We use frequent shopper purchase data of 4,081 shoppers across a thirty-month period combined with promotional data from the grocery chain’s weekly circulars to measure consumer response. That is, we assess the effect on sales resulting from the display of nutrition promotions in addition to price promotions in the weekly circular. We define nutrition promotions as the display of a summary nutritional score (NuVal score) next to a product featured in the weekly circular. Price promotions are defined as the display of discounted prices featured in the circular. We examine if shoppers’ price promotion sensitivity is affected by heightening the salience of nutritional information via featuring nutrition promotions in the circular. Importantly, we examine the moderating effects of shopper characteristics (nutrition consciousness and share-of-wallet) on these nutrition and price promotion sensitivities.

One additional distinguishing aspect of our work is the examination of the impact at the category-level (rather than product-specific) price and nutrition promotions. That is, we assess the effect of a price promotion or a nutrition promotion for apples (NuVal score=96) in the circular on the sales for all products in the produce category (not just the sales of apples). We predict that price promotions will have a significant positive impact on category-level sales (H1), because they will increase shoppers’ attention to the category even though

"..."
they might decrease attention and search in other categories (Fong et al. 2016; Tam and Ho 2006). Importantly, we predict that featuring nutrition promotions in the category in addition to the price promotions will lead to an additional increase in sales (H2). In addition to bringing further attention to the category, nutrition promotions should also lead to more favorable evaluations of the category because research has shown positive associations between nutrition claims and favorability of product evaluations and purchase intentions (Andrews et al., 1998; Berry et al., 2017; Burton et al., 1999; Keller et al., 1997; Kozup et al., 2003). We further predict that the effect of nutrition promotions on sales will be stronger for shoppers with higher nutrition consciousness (H3), since such shoppers react more positively to the provision of nutrition information at the point-of-sale (Andrews et al., 2011). Finally, we hypothesize that the effect of price promotions on sales will be stronger for shoppers with higher share-of-wallet (H5), because the featured nutritional information will be less novel for heavy users.

We test our hypotheses using the purchases of 4,081 shoppers in four categories (meat, produce, seafood, and bakery) across a thirty-month period. First, to test of H1 and H2, we conducted a multiple regression in which the total weekly category sales were predicted by the availability of price promotion and nutrition promotion in the circular (both coded as 1=ye, 0=now), three category dummy variables to capture differences in sales across the categories, and a trend variable (week number) to account for seasonality. Results (Table 1) support H1 and H2, showing that price promotions (b=5137.08, $<.0001) and nutrition promotions in the circulars (b=4088.04, $<.0001) increases total category sales. It is worth noting that the magnitude of the two effects is similar; simply adding nutritional information in the circulars leads to an additional increase in category sales of S4.088 per week on average.

Next, we looked at the disaggregated transaction-level data (3.5 million transactions) and conducted a similar regression on the total sales per transaction. Results (Table 2) were substantively similar: the effect of price (b=.154, $p<.01) and nutrition promotions were both positive and significant (b=.132, $p<.01), supporting H1 and H2.

To assess the moderating effect of shopper’s nutrition consciousness, we calculated the average quantity-weighted NuVal score of each shopper’s purchases across the 3-month period. In support of H3, we find that the increase in category sales resulting from the display of the nutrition promotions in the weekly circular is stronger among highly nutrition conscious shoppers (b=.002, $p<.0001). Interestingly, we also find a significant negative nutrition consciousness x price promotion interaction (b=-.007, $p=0.0001), suggesting that highly nutrition conscious shoppers react more negatively to price promotions but more positively when such promotions are accompanied by nutritional information.

To examine the moderating effect of shopper’s share-of-wallet, we calculated each shopper’s average monthly total basket purchases at the store. H4 and H5 are supported: Shoppers with higher share-of-wallet react more positively to price promotion (b = .062, $p<.0001) and negatively to nutrition promotions (b = -.037, $p<.0001).

Planned follow-up experiments will examine the mechanisms underlying these effects and test ways in which the effectiveness of nutrition promotions can be strengthened among shoppers with lower nutrition consciousness and higher share-of-wallet.

SESSION OVERVIEW

This session examines and expands concepts central to the study of co-creation in consumer research. Over the past two decades, co-creation has emerged from a call for customer involvement in product and service development (Prahalad and Ramaswamy 2000) to a philosophy that influences business practices across diverse industries and marketing processes. However, marketing and consumer research must move beyond conventional theorizations to develop new and more nuanced explanations of the social and material processes of value co-creation (Humphreys and Grayson 2008; Cova, Dalli, and Zwick 2011; Ostrom et al. 2015).

Vargo and Lusch (2004, 2016) argue that consumer value is always co-created, since it is realized only in use, or consumption, rather than in production. This concept of value-in-use aligns with a more holistic, culturally-oriented understanding of co-creation processes than theories emphasizing utility and value-in-exchange (Holbrook 1998; Arnould 2005; Schau, Muñiz, and Arnould 2009). The papers in this session review and extend the collective wisdom offered by sociocultural theories of value co-creation and probe more deeply into the theoretical issues surrounding the co-creation of consumer value and customer experience. The authors examine phenomena that challenge conventional co-creation theory and enable richer theorizations of value-in-use and consumer experience. Through a diverse range of study contexts, the session asks two interrelated questions. First, what is the nature of co-created value? Second, following the assertion that all value is necessarily co-created (Vargo and Lusch 2016), what social and material relationships explain consumer experiences in an increasingly participatory and consumer-centric (Firat and Venkatesh 1995) market environment?

The first two papers examine how consumer mythologies are co-created through social and material interactions that occur within and on the fringes of the market. Thomas and Mitchell study the co-creation of neighborhood brands, tracing the evolution of brand mythologies over time through interactions between marketers and consumers. Warren and Price analyze the processes by which consumers create and sustain value in wilderness experiences by aligning with the market-dissociated “dirtbag” mythology and co-opting market resources. The final two papers extend theories of value-in-use, by examining competition and complementarity between consumer activities in co-created consumer experiences. Godfrey and Wallendorf study value in retail servescapes as a consumer experience that emerges from heterogeneous consumption practices overlapping in time and space. Grant and Dacin develop the concept of “playbour” to explain the process by which value emerges through consumer experiences of competitive play and labour on the co-production platform Threadless.

Taken together, these papers develop conceptual conversations that are needed to more fully understand consumer value and customer experiences, which will become increasingly relevant and important as the conventional lines separating production and consumption continue to blur.

Co-creating Neighborhood Brands

EXTENDED ABSTRACT

Storytelling is critical to understanding how a cultural brand is co-created through marketer-consumer dynamics (Fournier 1998; Holt 2002, 2004; Holt and Thompson 2004; Schouten and McAlexander 1995). Consistent with notions of value created through market interactions (Vargo and Lusch 2008), cultural branding theory asserts that brands themselves come into existence to the extent that they are woven into stories ‘authored’ by market actors (Holt 2004). For example, consumers act as authors as they ritually draw on brands to resolve identity burdens generated by contradictory desires (Holt 2002, 2004; Holt and Thompson 2004; Thompson and Tanbyah 1999). Alternatively, marketers act as storytellers when they weave together culturally resonant notions of place to situate brands and market offerings (Cayla and Eckhardt 2008; Peñaloza 2000; Thompson and Tian 2008). In this sense, a cultural brand is an evolving story continually re-worked by both marketers and consumers in keeping with their respective needs.

While offering a powerful explanatory framework, certain assumptions of the cultural branding paradigm fall short in explaining ways in which particular cultural brands are co-created and co-produced in the marketplace. First, the cultural branding paradigm suggests an active role for marketers, consistent with previous literature on co-creation of brands, through developing “value-adding activities and experiences for the customer” (Payne et. al. 2009). In this way, the brand is co-created through marketer efforts to create a setting for optimal consumer experiences (Prahalad 2004). Cultural branding adds to this view by focusing on how marketers construct brand stories that perform identity myths that consumers can use to resolve anxieties over social contradictions (Holt and Thompson 2004; Luedicke, Thompson, and Giesler 2010; Thompson and Tian 2008). However, we have little work examining how cultural brands are co-created and maintained over time when marketers cease to be engaged in managing mythic storytelling and controlling a brands message (Muñiz Jr. and Schau 2005).

Second, while cultural branding proponents suggest a paradigmatic move away from the tenets of liberatory postmodernism (Holt 2002), cultural branding still largely assumes a degree of freedom on the part of consumers to appease divergent aspects of their fragment-ed identities through available options in the marketplace (Firat and
Venkatesh 1995). However, certain forms of consumption, while derived from identity concerns, are constrained in terms of consumers’ ability to engage in storytelling to access disparate identity myths (Askegaard and Linnet 2011; Giesler and Versuus 2014; Zwick, Bon-su, and Darmody 2008). Recent work in the area of branded places suggests that physical and spatial dimensions of a brand may contribute to this constraint (Castilhos 2019), as do collective framing influences from a wide array of stakeholders (Arvidsson and Calandro 2016; Kates 2004).

Through an exploratory ethnographic investigation of two planned neighborhood developments, we seek to extend and enrich the cultural branding theory by helping to explain the multifaceted ways in which the central mythologies of cultural brands are co-created amongst a diverse array of stakeholders. We also analyze the maintenance and evolution of the neighborhood brands as the central storytelling, brand managing role shifts gradually over time from the neighborhood developer (the marketer) to the neighborhood residents (the consumers). Our data collection is ongoing and includes a combination of depth interviews, observational techniques, photography, and text sources including news articles, marketing materials and government documents. To date, 40 semi-structured interviews have been conducted with the developers and residents of two planned neighborhoods, in the Midwest and Southeastern United States.

Our preliminary analysis shows that mythical storytelling plays a key role throughout the development of a neighborhood in selling the lived experience to consumers. The multiple stakeholders in this context create both challenges and opportunities for the marketer as they work to establish the brand identity, which is gradually handed over to the homeowners as the individual houses are sold. This storytelling is managed primarily by the developer and passed down to real estate agents, who must convey that meaning to prospective homeowners. In both neighborhoods, these brand myths are influenced and shaped by local histories, in an effort to preserve cultural meaning the land held before physical construction began.

This type of marketer-consumer relationship is unique in that the transfer of ownership and the co-production dynamics of the brand meaning shift slowly over time, until the marketer no longer has any control over the brand. However, in cases where the developer is building their own firm’s brand as they pursue other properties, the outcome of the neighborhood continues to influence their reputation long after they have left the neighborhood. Therefore, it is in their interest to develop a strong cultural brand that will extend beyond their presence in the development.

We find that as residents become the purveyors of brand meaning, they work within the given brand framework, but incorporate meaning from their own experiences in the neighborhood and their individual beliefs about neighboring and community. As they assume control over the brand, residents build upon or depart from the original narrative to make sense of outcomes in the neighborhood, relative to their expectations. For example, some residents reconstruct the cultural myths to alleviate contradictions between the brand and a lack of fit with the existing culture.

Additionally, our data reveals that local officials, businesspeople, and interested citizens influence brand meaning by presenting counter-narratives regarding the neighborhood development. Motivations for resistance include concerns about environmental damage, respecting local traditions or culture, and possible increases in traffic or crime. As the brand narratives are tested by these outside actors, marketers are challenged to more clearly convey cultural legitimacy of the neighborhood brand and demonstrate its congruity with the existing culture.

We contribute to a more nuanced understanding of how cultural brands are collaboratively co-created through interactions amongst a diverse array of market stakeholders. In this research, neighborhood marketers, resident consumers, and external stakeholders co-create the neighborhood brand by co-authoring cultural narratives based in local history, images portraying the “good life” (Holt 2004), and residents’ own ideas of what neighboring and community involve.

**Trickster Consumers: Consumed by Passion**

**EXTENDED ABSTRACT**

We examine a field of consumers who use marketplace mythology to address the conflict between their pursuits-of-passions and presumed market rewards. Consistent with neoliberal ideologies, numerous career guides, as well as successful business people, entrepreneurs, scholars, artists, and athletes, encourage pursuits-of-passions as the pathway to marketplace rewards (Hong 2015; Taylor 2015). However, the consumers we focus on align themselves with the ‘dirtbag’ marketplace mythology, which celebrates wilderness pursuits-of-passions, without regard for marketplace rewards (Chouinard [2005] 2016; Holt and Cameron 2010). Examining the dirtbag mythology through the theoretical lens of the archetypical trickster is uniquely useful in understanding how consumers reinterpret, convert and invert marketplace resources in order to resolve tensions between their passion-driven identities and their subsequent dissociation from markets. While the trickster’s pursuits-of-passions occur without regard for society, the inevitable conflicts between the trickster’s individualism and society’s structures lead to destructive and rejuvenative disruptions. These disruptions are temporarily resolved as society creates new structures in response to the trickster, causing a recurrent co-creative cycle.

Previous research describing the power of mythologies in co-creative cultural branding has overlooked the trickster archetype, instead focusing on heroes, outlaws, and rebels (Belk and Costa 1998; Holt and Thompson 2004; Kozinets and Handelman 2004; Luedicke et al. 2010; Schouten and McAlexander 1995). Theoretically, we contribute to research on marketplace mythologies by introducing the trickster archetype as a cultural resource for resolving contradictions between individualistic passions and marketplace rewards. Distinct from the gift-bearing hero, the oppositional rebel and the outlaw seeking escape from society, the trickster is not primarily defined by his relationship to society. The archetypical trickster is primarily defined by uninhibited pursuits-of-passions, and secondary by the tricks he plays on society. These tricks enable the trickster’s pursuits-of-passions, allow the trickster to live inbetweensociety and the wild, and lead to unintentional disruptions of the social system (Babcock-Abrahams 1975; Carroll 1984; Hyde [1998] 2010). The trickster consumer imagines market relationships and exploits market resources in order to survive and thrive inbetween markets and the wild. Figure 1 models the Trickster’s disruptive and co-creative market impact.

Managerially, the trickster archetype is an important co-creative cultural resource for brands, especially in the $412b consumption field of outdoor recreation (Bureau of Economic Analysis 2018). Prominent outdoor brands rely on “core consumers,” who align
themselves with the trickster/dirtbag marketplace mythology, for their branding, personnel and product development (Chouinard [2005] 2016, 92; Harrison and Corley 2011; Holt and Cameron 2010). For example, early mountain bikers, who self-identify as dirtbags, inadvertently co-created the modern mountain bike industry. They built secret illegal trails on federal, state and private land. As trails improved, demand for bikes and trail access increased, leading to the co-creation of new industries, including the economic revival of rural communities and the development of online mapping platforms (Evens-Brown and Quimby 2019). Similar to the trickster’s role as accidental culture-creators, dirtbag consumers are accidental co-creators of the booming outdoor industry.

This project uses a broad range of ethnographic data to understand wilderness consumers who self-identify with the term “dirtbag.” The data includes seventeen semi-structured interviews, follow-up communications, nine informal interviews conducted at the “Dirtbag Derby” climbing competition, ethnographic field notes, and netnographic data from social media platforms. Secondary sources were used to better understand how the enic data fit into popular narratives of “dirtbags,” wilderness consumption, and outdoor brands. These sources, often sponsored by outdoor brands, include popular press, documentary films (e.g., Dirtbag: The Legend of Fred Beckey, O’Leske 2017), blogs and many episodes of The Dirtbag Diaries podcast.

Findings reveal that certain consumers assuage the conflict between their individualistic wilderness passions and lack of marketplace reward by embracing the dirtbag marketplace mythology. These consumers report their pursuits-of-passions to be the singular motivation for their interactions, and lack of interactions, with markets. They consider market structures—such as shelter, food, family, and cleanliness—secondary considerations to be freely reimagined, redefined, and repurposed, in order to further their pursuits-of-passions. Lolo (36F), a brand-sponsored snowboarder and proud self-identified dirtbag, boasts of “evicting” her child (now eight years old) from her womb before winter so she could go “shred” on her snowboard. Every winter, she moves into a van that she illegally parks in ski-resort parking lots, 1,000 miles from her husband and son. She reports that her fellow snowboarders and her husband support her decisions. Reimagining the meaning of clean and dirt, Dusty (22F) describes rubbing sand through her hair to get rid of the grease accumulated after a week climbing in the desert.

Disassociating from markets and playing tricks on market structures enables our informants to live indefinitely inbetween markets and the wild, and ultimately causes marketplace disruptions and the co-creation of new market structures. Trinity’s (43F) ambivalence to market structures is expressed in her strong desire to own a home, while simultaneously feeling imprisoned when she sleeps under a roof, even in her own bedroom. Her belief that the “real world” is the wilderness, and her recurrent need to work in a “front country” office to sustain her wilderness pursuits, further emphasizes her indefinite inbetweeness. Other informants disruptively redefined home, defining home as living in cars, tents or sleeping on dirt. Ethan (20M) describes living in his car near a river using the metaphor of a two-story home. He believes that dirtbags have influenced mainstream market actors, who have adopted the hashtag #vanlife, which has 4.6m posts on Instagram. #Vanlife celebrates the aesthetic, experiential, and material value co-created by consumers and producers in the booming van-dwelling marketplace.

We find that trickster consumers disruptively co-opt market resources to produce personally valuable experiences. This causes creative cycles of value creation, iterating between consumers and producers.

Value in Heterogeneity: How Servicescape Experiences Emerge From Divergent Consumption Practices

EXTENDED ABSTRACT

A growing body of theory reconceptualizes value as a sociocultural construct, rather than an economic output. Instead of being something produced for consumers, “value is idiosyncratic, experiential, contextual, and meaning laden” (Vargo and Lusch 2008, 7), and is realized during use or consumption as “an interactive relativistic preference experience” (Holbrook 1998, 5). theorizing consumer value as a sociocultural construct enables more holistic explanations of many consumption phenomena, including consumer experiences in physical spaces. In this paper, we build a spatial theory of value co-creation by studying consumer experiences in a servicescape that facilitates overlapping and heterogeneous consumption practices.

Value is “a function of the interaction between subjects, or between a subject, and an object... and resides in the consumption experience” (Echeverri and Skålén 2011, 353). As such, value is experienced individually, and in both negative and positive ways, as consumers interact with multiple actors involved in the provision (or destruction) of a service (Tax, McCutcheon, and Wilkinson 2013). Thus, the creation of consumer value always arises during the enactment of consumption practices (Grönroos and Voima 2013). Shove et al. (2012, 133) also argue that “places are defined by practices,” which are routinized patterns of human activity organized around interactions between cultural and material resources (Schatzki 2001, 2002; Reckwitz 2002). Theories of practice acknowledge and examine the co-constitutive nature of human action and the external social and material structures that facilitate that action (Warde 2005).

Practice-oriented thinking calls for a novel practice-based examination and conceptualization of value within the physical market environment, or servicescape. Research examining consumer experiences within servicescapes typically focuses on the facilitation of a single overarching consumption practice (Arnould and Price 1993; Dion and Borraz 2017) or a set of practices guided by an overarching cultural logic (Kozinets et al. 2004; Thompson and Arsel 2004; Borghini et al. 2009). However, as market spaces break from standardized services and layouts (Aubert-Gamet and Cova 1999), consumption practice heterogeneity plays an increasingly important role in servicescape theory and management. For example, the practices of work or study at coffee shop tables reduces the positive value experienced by consumers enacting different consumption practices (Griffiths and Gilly 2012), and the practice of walking with a stroller can disrupt the schedule and routines of service providers and other consumers riding a crowded tram (Echeverri and Skålén 2011). In other words, certain configurations of practices in a servicescape may facilitate the co-creation of positive value for some consumers, while inducing negative value to emerge for others.

In this paper, we examine the ways that value is co-created through interactions between the places, things, and people—including consumers and service providers—involving in the enactment of heterogeneous practices within a servicescape. We use ethnographic and spatial survey methodologies to look more closely at the lived experience of consumers within a space that facilitates heterogeneous consumption practices, including the cultural and material resources the practices draw upon.

Our analysis is based on four years of participant observation at a mixed-use retail center in U.S. Southwest, and also includes an open-ended “sketch map” survey (Brennan-Horley and Gibson 2009; Boschmann and Cubbon 2014) and governmental spheres of planning and economic development policy. In response we discuss here how qualitative methods can be used to address such concerns,
based on experiences from an empirical project charged with the task of documenting creative activity in Darwin - a small city in Australia’s tropical north. Diverse creative practitioners were interviewed about their interactions with the city - and hard-copy maps were used as anchoring devices around spatially orientated interview questions. Results from this interview-mapping process were accumulated and analysed in a geographical information system (GIS). These sketch maps extend the reach of our ethnographic data by “collecting unique spatial data of individual experiences, visualizing socio-spatial processes, [and] breaking down particular barriers of positional identity in research” (Boschmann and Cubbon 2014, 237). The study site, a small retail center located in a gentrifying urban neighborhood, blends together free concerts, bakeries favored by working-class neighborhood residents, and a low-income-focused farmers’ market with posh boutiques and upscale restaurants. This unique mix provides ideal conditions for studying the ways that heterogeneous practices shape consumer experiences within a servicescape. Ethnographic data include field notes, photographs, and formal and informal interviews with consumers, managers, and service providers. Additionally, eighty-three consumers participated in the sketch map survey, allowing us to use GIS software to analyze the spatial relationships between the locations of multiple practice enactments and the experiences consumer had enacting their own practices. We find that the overlapping enactment of heterogeneous consumption practices can have both positive and negative influences on consumer experiences. The value experienced by consumers enacting practices within the servicescape is shaped by the alignment of material and cultural resources used by overlapping practices. Conflict over material resources shared by multiple practices, such as space, furniture, or retail products, is a necessary condition for the emergence of both positive value (between complementary practices) and negative value (between conflicting practices) in consumer experiences. The complementarity of consumption practices depends on alignments of cultural resources deployed by consumers enacting these practices. Practices enacted following a market logic, such as holding business meetings or shopping for produce, exert a negative influence on the value experienced by consumers enacting practices that share material resources but follow non-market logics. Practices guided by non-market logics have a similar effect on market-oriented practices, such as dogs barking while walked by their owners between consumers eating at restaurant tables. Consumer sketch maps indicate that practice complementarity plays a prominent role in shaping consumer experiences.

Our results illustrate that value co-creation in the servicescape is a process outside the direct control of service providers and managers, who must exert their influence indirectly by facilitating specific practice configurations through servicescape design. These designs, however, are always open to interpretation by consumers who use market spaces in unanticipated ways, creating both serendipitous complementarities and unpredictable conflicts as they enact heterogeneous consumption practices. Our analysis contributes a more holistic understanding of the sociocultural factors that shape consumer servicescape experiences. The sketch map method also demonstrates an explicitly spatial analysis of the links between consumption practices and consumer experience.

**Understanding Co-Creation Through a Playbour Lens**

**EXTENDED ABSTRACT**

The notions of play and of labour were often thought of as contradictory and distinct (c.f., Marx 1909). However, a more recent perspective, the Californian Ideology (Barbrook and Cameron 1996), emphasizes that we live in a new economy where the conflict between labour and capital is melding, and in which playfulness is emerging within the labour of a creative class. In the past decade, companies began creating online co-creation platforms engaging consumers in a playful manner through such activities as design competitions (e.g., Lego Ideas, Doritos Crash the Superbowl, Threadless). Further, the increasing digitalization of labour processes has also brought with it increased playfulness, and gamification in cultural practices and work activities (Ferrer-Conill 2018; Khaled 2014; Raessens 2006) as well as literature extolling the benefits of gameful and playful experiences in the workplace (Torhonen et al. 2019).

One area in which marketers are witnessing this melding is co-creation. For some, co-creation empowers consumers to construct and shape their own consumption experiences, and provides them opportunities to connect and share experiences with like-minded others in a community (Prahalad and Ramaswamy 2004; Vargo and Lusch 2004), democratizing the marketplace with consumers who are “empowered, consulted, knowledgeable and liberated” (Parsons, Maclaran, Chatzidakis 2017, p. 6). For others, co-creation is an exploitative relationship between firms and consumers (Cova and Dalli 2009), characterized by unpaid labour and constituting forms of control and exploitation (Cova, Dalli, and Zwick 2011). However, as Cova et al. (2011, p. 235) note, “the creative and voluntary work of co-creation can be reduced neither to passive consumerism nor to the insidious manipulation of capitalists,’ suggesting the melding of perspectives is necessary for characterizing co-creation. In our research, we adopt and apply such a theoretical lens in examining an online co-creation platform.

Stemming from the Californian Ideology, our theoretical lens draws upon the concept of “playbour” (Kucklich 2005)—a hybrid concept derived from play and labour describing a type of unpaid labour that gives the perception that it is a leisure activity, or an extension of play (Kucklich 2005). Playbour is useful in “describing the convergence of mechanisms that drive fans to engage in play that is highly profitable for the entertainment industries, yet is seldom remunerated” (Goggin 2011, p. 358). In the digital gaming realm, researchers use the concept to examine the common occurrence of individuals expending extensive time and labour in creating computer game modules and extensions (Goggin 2011; Torhonen et al. 2019).

Understanding playbour relies on understanding the concepts of play and labour, and their relationship. Huizinga (1938/1955) defines play as intense and absorbing, transcending the immediate needs of life, having to do with the imagination, and being joyful because it provides a hiatus from the seriousness of daily life. For some researchers, play must occur naturally and cannot be forced (Ferrer-Conill 2018), thus, “a game which one would be forced to play would at once cease being play” (Caillois 1961, p. 195). Based on this perspective, scholars have long established play as a form of escapism and self-distraction from the burden of labouring processes (Marcuse 1933/1973). Play has “no material interest, and no profit can be gained by it,” hence it is autotelic (Huizinga 1938/1955, p. 13). Labour, by contrast, revolves around an agreement between an employer and employee to generate value though productive processes (Thompson 1989). With organizational goals at the core of labour, scholars argue that labour can hardly nurture genuine playful attitudes (Ferrer-Conill 2018).

Yet, the confluence of technological advances in online marketing strategies, along with the digitization of the labour process, has given way to an environment in which playfulness is adopted within the tools of digital labour (Ferrer-Conill 2018). The historical dichotomous understanding of the theoretical understanding of play and labour seem much less binary in practice. The concept of playbour
(Kucklich 2005) as a theoretical lens emerges as a way to conceptualize of the relationship between consumers and firms in the context of an online co-creation platform where play and labour co-exist. In this lens, the fusion of play and labour articulates redefined cultural and social connections (Ferrer-Conill 2018) between consumers and firms to unpack broader developments in an evolving understanding of capitalism (Cova et al. 2011).

Our data consist of a netnography and depth interviews with members of an online co-creation community formed around Threadless, a community-based company depending entirely on the participation of members to create designs to print and sell on Threadless products.

Two themes emerge in our preliminary findings that characterize co-creation through the playbour lens. First, we find that play is an important and expected element in consumers’ motivation to participate. Our informants note spending countless hours engaged in creating designs. For most informants, who tend to be university educated with professional careers and young families, engaging in this co-creation community provides an escape from their hectic lives. Losing themselves in the creation to exist in the moment are foundational characteristics of play (Gadamer 1975). In this way, engaging with the community provides value in-use to participating consumers (Vargo and Lusch 2004).

Second, we observe that play maintains consumers’ motivation to participate despite sometimes feeling frustrated toward the firm and even couched these frustrations in exploitative language. Based on informants’ reports, although Threadless has explicit rules for the competition, it is through understanding the competition’s nuances and implicit rules that participating consumers are successful at the competition. In the end, while the competition is a primary source for value creation for the firm, it is also a catalyst for consumers to create and derive value in playfully engaging with the community to better understand the competition’s nuances.

Our work enlightens the relationship between play and labour in an online co-creation community. We find that play is an important mechanism in successful value creation, which propels and maintains the elements of labour inherent in the co-creation platform.

Paper #1: (Trans)Women Are Wonderful?
Broderick Turner, Northwestern University, USA
Galen V. Bodenhausen, Northwestern University, USA

EXTENDED ABSTRACT
Transgendered individuals experience both increased acceptance and dangerous discrimination. There are positive global shifts in the attitudes towards transgendered individuals such as a recent global, in which the majority of respondents believed in banning discrimination against transgender people (Flores, Brown and Park 2016). However, transgendered individuals report experiencing significant discrimination (Harrison et al. 2012). Indeed, work using a modified version of the implicit association test for attitudes towards transgendered people (IAT; Wang-Jones et al. 2017) found that people may express an explicit acceptance of transgendered people, but still hold a negative implicit attitude towards this group. A glaring omission in the work on transgender evaluations is the consideration of the direction of the transition, i.e. do attitudes towards transgender individuals depend upon the direction of transition such that individuals identified as male-to-female (MTF) or female-to-male transgender respondents (FTM), may be evaluated differently?

Early work on gender and judgements established women are evaluated more positively than men. With this finding, known as the “women are wonderful” effect (Eagly and Mladinic 1989), researchers have determined that women are judged to be more warm and trustworthy than men. Work on gender categorization also finds that the binary gender categorization is one of the first social categorizations, along with age and race, that people are able to make (Maccoby 1988). An observer can accurately assess whether a person is male or female, even when a person’s hair and eyes are concealed (Bruce et al. 1993). This ease of categorization is due to a strong difference in the prototypical features that make up a face. Adult male and female face are defined prototypical features for males include lowered eye-brows ridges, greater facial angularity, protuberant noses, and prominent chins, whereas women have higher eye-brow ridges, lighter skin texture, rounder faces and non-prominent chins (Bruce et al. 1993; Bruce and Young 1998).

However, for transgender individuals who transition from male to female, the male prototypical features are more difficult to reverse (Ettner, Monstrey, and Coleman 2016). However, in the transition from female to male, the male prototypic features can be induced by hormone replacement such that a FTM who is fully transitioned loses many of the female facial features and is able to gain some of prototypic male features. A MTF may be able to gain many of the non-facial female prototypic features (breasts, hips, longer hair), yet they continue to carry the prototypic male features in their face (Ettner, Monstrey, and Coleman 2016). Thus, we hypothesize that when categorizing MTF, people reflexively use their biological gender markers, and judge them the same as CIS gendered men. However, FTM do not have the same underlying biologically male facial features, but do have secondary male features, and because the male categorization is salient, these faces should be judged as more trustworthy than CIS men and FTM, but less trustworthy than CIS women faces.

In concert, these four papers highlight the importance of examining the psychology underlying how antecedents that lead to injustice, while also exploring the effect of injustice on consumers. This session not only provides novel theoretical insights, but also has critical practical importance. We hope that this session will have a broad appeal to researchers studying injustice in its many forms.

SESSION OVERVIEW
Consumers must contend with societal injustice towards their identity, (i.e., their race and gender), and their actions (choice of romantic partner). In this session, we provide novel research from four papers that explore the processes that lead to societal injustice (Papers 1 and 2), how experiencing injustice shifts consumers’ behavior (Paper 3), and how disclosing yourself as the victim of sexual injustice changes the perception of other consumers about one’s experience (Paper 4). By examining both the psychological processes that lead to those outcomes and the corresponding behavioral outcomes, this session can open new avenues for research on consumer injustice.

Paper 1 explores an explanation for the mistreatment of transgender individuals, and finds that the difficulty in transitioning from male to female (vs. female to male) leads to a deviation in the evaluation of transgender faces, such that transgender women are judged more harshly than CIS gender women, or transgender men, but similar to CIS gender men. It is the first paper in to use a visual scale to unearth this difference in gender identity evaluations.

In, connecting societal changes to injustice, Paper 2 finds that perceptions of an increasingly diverse America, through the rise of interracial marriage actually increases racial bias. Paper 3 finds that consumers who are victims of injustice exhibit a higher need to belong and exert more effort to connect with acquaintances and strangers than fairly treated peers.

Finally, Paper 4 explores the perception of self-disclosure of the injustice of sexual assault and explores how this admission interacts with the gender of the perceiver. Their research finds a divergent pattern in response to the self-disclosure of a victim, such that women give less money to victims (as compared to a control), while men give more.

In concert, these four papers highlight the importance of examining the psychology underlying how antecedents that lead to injustice, while also exploring the effect of injustice on consumers. This session not only provides novel theoretical insights, but also has critical practical importance. We hope that this session will have a broad appeal to researchers studying injustice in its many forms.

An increase in interracial marriage increases racial bias

EXTENDED ABSTRACT

Just over fifty years ago, the U.S. Supreme Court invalidated remaining state laws enforcing racial segregation in marriage and intimate relationships (Loving v. Virginia, 1967). Since then, interracial marriage has become increasingly common, roughly 15% of new marriages in 2010 were interracial (Wang, 2012). Further, polling data suggests that Americans are increasingly accepting of interracial marriage (Hayes, 2012). Taken together, it appears that in the U.S. interracial marriage has transformed from a criminal offense into an accepted practice in just 50 years. Despite these rapid changes in the prevalence of interracial marriage biases against interracial couples remain (Skinner & Hudac, 2017; Skinner & Rae, 2018), and little is known about how the rise in interracial marriage may impact Americans’ attitudes, preferences, and identities. In this study we address how the increasing rate of interracial marriage affects White Americans’ racial attitudes and openness to interracial relationships.

Although the rise in interracial marriage is often heralded as a sign of declining racial bias in the U.S. (Jones, 2011), no work has examined how changes in the prevalence of interracial romance are impacting racial biases. Previous work examining the impact of increasing racial diversity provides a pessimistic view. Sociological theory posits that increased minority proportions can threaten the majority groups’ values, status, and power, thereby inciting intergroup bias among majority-group members (Blalock, 1967; Quillian, 1996; Taylor, 1998). Similarly, research shows that White Americans who live in areas with larger proportions of racial/ethnic outgroup members tend to show higher levels of racial/ethnic bias than those who live in more racially homogeneous areas (e.g., Rae, Newheiser, & Olson, 2015). Moreover, merely exposing White Americans to information about the increasing racial/ethnic diversity in the U.S. can increase racial/ethnic biases (e.g., Skinner & Cheadle, 2016; Craig & Richeson, 2014). Insofar that the increase in interracial marriages reflects a relaxation of racial boundaries and an impending increase in racial diversity (i.e., more mixed-race children), interracial marriages may pose a threat to White Americans. Thus, the increase in interracial marriage may increase racial biases among White Americans (Hypothesis 1).

We tested this hypothesis in a sample of non-Hispanic White American adults (N = 670) from the Project Implicit research pool. Project Implicit is an educational outreach organization that operates a website where people can complete attitude measures towards various social groups, including one that assesses Black-White racial attitudes. Each year, more than one million people (mostly U.S. residents) provide their Black-White racial attitudes via Project Implicit. In this study respondents were randomly assigned to read a brief news style article emphasizing the increase in interracial marriage since it was legalized or no article (control condition). The stable rates of interracial marriage article focused on a city in which interracial marriage is still fairly uncommon (i.e., Asheville, NC), emphasizing how little rates of interracial marriage have changed since it was legalized. In the other condition the article focused on a city where interracial marriage rates are among the highest in the country (i.e., Fayetteville, NC), emphasizing how much rates of interracial marriage have increased since it was legalized (see Balwit, 2017). Similar approaches have been used in previous studies to manipulate salience of increasing racial diversity (e.g., Craig & Richeson, 2014; Skinner & Cheadle, 2016). As predicted, results indicated that respondents who read about increases in interracial marriage rates showed greater implicit and explicit anti-Black biases than participants in the control condition. Thus, initial evidence suggests that increasing interracial marriage may increase racial biases among White Americans. These findings suggest that depictions of interracial marriage in the media may have important implications for racial attitudes and the racial climate in the U.S.—potentially heightening racial biases among racial majority group members.

Reach out in the Darkness: How Unfair Treatments Shape Social Connection Motivation

EXTENDED ABSTRACT

A considerable portion of research is in the context of justice, and much has focused on how different psychological factors influence consumers’ perception of justice, particularly the fairness of prices (e.g., Bolton and Alba 2006; Bolton, Keh, and Alba 2010; Bolton, Warlop, and Alba 2003; Campbell 1999, 2007; Haws and Bearden 2006; Jin, He, and Zhang 2014; Xia, Monroe, and Cox 2004). However, the influence of experience of injustice on unre-
lated consumer behaviors is still largely unknown. The current research attempts to fill this gap of knowledge through investigating the impact of injustice experiences on consumers’ desire for social connectedness.

Experience of injustice may lead to many negative consequences, such as retaliation (Brebel, De Cremer, and Sedikides 2008), negative feelings such as anger, fear, guilt, and shame (Mikula, Scherer, and Athenstaedt 1998), health problems like depression (Kessler, Mickelson, and Willams 1999) and distress (Schulz et al. 2000), and even anti-social behavior (Greenberg 1993). Given the fundamental role of justice in human life (Tolman 2006), it is not surprising that people develop an inherent need to believe in a just world in which everyone gets what they deserve and deserves what they get (Lerner 1965, 1980; Fischer and Skitka 2006). This justice belief can also be categorized as an important personal resource that helps people to cope with various negative events that occur in daily life (e.g., Dalbert 2001, 2009; Montada 2003).

Facing violation of this belief, such as unjust or unfair events (Hafer and Begue 2005), while there has been plenty of evidence for the within-domain compensation by maintaining the integrity of their personal belief in justice (Haynes and Olson 2006; Hafer 2000; Callan, Kay, Davidenko, and Ellard 2009; Jost, Banaji, and Nosek et al. 2010), there are alternative ways to compensate for this resource deprivation. Social connection, as interpersonal resource (Correll and Park 2005), can be substituted for or replaced by other types of psychological resources, for example financial resources (Duclos, Wan, and Jiang 2013). People also use social connection to compensate for lack of resources in other domains. For instance, the lack of social power and social status has been found to increase the need to belong, which represents an individual’s desire for social connectedness (Waytz, Chou, Magee, and Galinsky 2015). Taken together, we propose that experienced injustice will threaten one’s belief in justice and make people feel a shortage or deprivation of psychological resources, which will subsequently lead to a higher desire for social connectedness.

Furthermore, we predict that self-esteem moderates the influence of injustice on the desire for social connectedness, because self-esteem, as a psychological resource (Stets and Cast 2007), could compensate for a lack of social connection (Baumeister and Leary 1995). Specifically, the influence of experienced injustice on the desire for social connectedness should be less prominent among people with high self-esteem compared to those with low self-esteem. One survey and two studies examined these possibilities.

In Study 1, we found the positive effect of injustice experiences on the desire for social connectedness by looking at consumers’ social networking behavior from a large-scale national survey (China Family Panel Studies). The experience of injustice was inferred from responses to four different unjust situations (“being treated unjustly because of the gap between the rich and poor, household registration, gender, and being treated unjustly by government officials”). As the dependent variable, we recorded the responses of interviewees to four items concerning their online and offline social networking behaviors.

Study 2 tested the effect of injustice experiences on the desire for social connectedness and the mediating role of perceived resource deprivation by measuring evaluation of an anthropomorphized product to examine consumers’ desire for social connectedness (e.g., Epley, Waytz, and Cacioppo 2007; Epley, Akalis, Waytz, and Cacioppo 2008). We expected that injustice experience would lead to a heightened evaluation of the anthropomorphized (but not the neutral) product. Mturk participants (N=293) were randomly assigned to a 3 (injustice vs. negative mood vs. control) X 2 (anthropomorphized vs. neutral) between-subjects design. In the injustice condition, participants recalled an unjust or unfair incident. In the negative mood condition, participants recalled a physically painful incident. And in the control condition, the participants recalled what they ate and drank yesterday. Then, participants reported to four-item measurement of resource deprivation (adapted from Callan, Shead, and Olson 2011). Finally, the participants evaluated either an anthropomorphized vacuum cleaner or a neutral vacuum cleaner. Consistent with our expectation, participants in the injustice condition gave a higher evaluation to the anthropomorphized product than those in both negative-mood condition and control condition, whereas the latter two conditions did not differ from each other. Moreover, this effect is mediated by perceived resource deprivation.

Study 3 tested the moderating role of self-esteem. Mturk participants (N=180) were randomly assigned to either an unfairness or a control condition. In the unfairness condition, participants were asked to recall a particular incident in which others had personally treated them unfairly, whereas participants in control condition were simply asked to recall the last grocery shopping experience. Then, we measured the social connection motivation of the participants using the Need to Belong Scale constructed by Leary et al. (2013). Finally, the chronic self-esteem of participants was inferred from their responses to the Rosenberg (1965) Self-Esteem Scale. As expected, unfair experiences increased the participants’ desire for social connection. Importantly, the effect was more salient when an individual’s self-esteem was low and was not evident when self-esteem was high.

In summary, experienced injustice increased consumers’ desire for social connection. Moreover, this effect is mediated by the feeling of resource deprivation, and moderated by consumers’ self-esteem. Our research is the first to show that past experiences of unfair treatments could induce potential “positive” consequences among victims. Our findings also provide further evidence that the social resources an individual possesses can serve as a buffer for the influence of threat and negative experiences.

**Perceptions of your #MeToo post: Men and women see it differently**

**EXTENDED ABSTRACT**

Sexual assault victims are often marginalized, shamed, and stigmatized into keeping silent about their assault (Weiss, 2010). Sexual assault is, unfortunately, a common occurrence in the United States with one in three women and one in six men experiencing sexual assault in their lifetime (Smith et al. 2017). Extant literature has focused on the impact of sexual assault on women’s physical and psychological health (e.g., Chivers-Wilson 2006). Sexual assault has been linked to post-traumatic stress disorder, depression, suicidality, and substance use (Campbell, Dworkin, and Cabral 2009). According to Campbell et al. (2009) “rape is one of the most severe of all traumas, causing multiple, long-term negative outcomes. Between 17% and 65% of women with a lifetime history of sexual assault develop post-traumatic stress disorder.”

Yet, in recent times, the “MeToo” movement has encouraged women across the world to share their sexual assault stories through social media. In fact, in October 2017, the #MeToo hashtag reached over 12 million posts on Facebook in under 24 hours (CBS News, 2017). This strategy of sharing sexual assault stories, coupled with positive social reactions and support from family, friends, and significant others, predicts less mental distress post-assault (Campbell et al. 2010).
Despite the prevalence of the #MeToo movement, little is known about how this type of self-disclosure is perceived by employers, buyers, or sellers. Whether perceptions of others are right or wrong, they are formed shockingly quickly; Willis and Todorov argue that we form first impressions within the first 100 milliseconds of meeting another person (2006). As such, it is possible to believe that a #MeToo disclosure will impact perceptions. For example, other types of self-disclosures, like motherhood, impact people’s perceptions of the woman’s competence, warmth, commitment, and effectiveness in the workplace (Correll, Benard, and Paik, 2007; Cuddy, Fiske, and Glick 2004).

The current research demonstrates that women and men respond differently when learning that a person has been a victim of sexual assault. In our experiment, sellers are introduced to the Facebook marketplace, a real online marketplace where Facebook users can buy and sell goods from one another. Through this real marketplace, buyers and sellers have the ability to click on users’ Facebook profiles. We used this marketplace for our experiment, a naturally occurring setting where buyers can learn more information about a seller’s posts on social media.

We recruited 126 participants (62% female) from a large Western university in exchange for a small monetary payment. Participants were asked to review a new Amazon gift card being sold on Facebook’s marketplace, as well as the seller’s profile. Participants were randomized into one of three conditions, each showing the same seller with a slightly different profile. The three conditions are the following: (1) the seller’s recent post disclosed a past sexual assault and their support for the #MeToo movement, (2) the seller’s most recent post was sharing (retweeting) a friend’s post containing the same exact content as in condition 1, and (3) the seller’s most recent post was about a recent concert, unrelated to #MeToo (our control). Participants then reported their willingness to pay for the Amazon gift card ($0-$100), as well as their perceptions of the seller’s competence, trustworthiness, threat, ability to reach a deal, and societal status.

Using a linear regression model, our results show a significant interaction between participants’ gender and our conditions on willingness to pay for the Amazon gift card (b= -29.34, t(120)=−2.25, p=.024). In the control, women offered $81.73 for the Amazon gift card, on average. However, when the seller disclosed their sexual assault, women offered just $61.90 (a 23.9% decrease) for the same gift card (p=0.023). In contrast, men offered $73.90 for the item in the control condition and increased their offer to $83.90 (a 13.5% increase) when the seller disclosed their sexual assault (ns). Additionally, compared to the control, women offered $70.90 (ns) to the seller who reposted another person’s sexual assault post, while men offered $76.40 (ns). This result shows early indicative evidence that the effect is borne by sexual assault victims, and not by allies who support them.

Additionally, men and women differ in their perceptions of the sellers’ societal status (not in their competence, trustworthiness, or threatening perceptions). We find a significant interaction between gender and our conditions on perceptions of status (b= -1.64, t(120)=−2.19, p=.030), such that on a 1-9 scale, women (men) perceive the seller to have lower (higher) status if their Facebook profile contains a #MeToo post compared to the control.

Our study shows that sharing a sexual assault experience could lead to both positive and negative societal outcomes, depending on the audience. The risk of negative societal outcomes when sharing a sexual assault story could contribute to explain why women often underreport their sexual assault experiences. Notably, we find similar patterns across men and women in other experimental contexts, such as when participants propose a starting salary for a job candidate after reviewing the candidates’ LinkedIn profile and Twitter feed.

SESSION OVERVIEW

Consumer decision-making often involves explicit or implicit tradeoffs between larger-later vs. sooner-small benefits (Bartels and Urminsky 2015, Bazerman et al 1998, Hoch and Loewenstein 1991, Thaler and Shefrin 1981). Intertemporal preferences have been studied using variants of hyperbolic discounting as a model for short-sighted decisions and failures of self-control (Ainslie 1975). This literature has debated how people value delayed rewards and how intertemporal preferences relate to consumer behavior, using a limited toolbox of research paradigms. Research on intertemporal choice has made great progress and our understanding of time discounting is now much richer than the simple hyperbolic discounting model. In the modern view, impatience is not only an individual difference, but varies by context: the same person will be more patient in some decisions and less patient in others. This variation has been discussed in terms that correspond to a dual-process view of decisions (Sloman 1996, Hoch and Loewenstein 1991, Loewenstein 1996, Baumeister 2002). In this view, people are impatient when they are rushed, resource-constrained, facing tempting options or deciding about small stakes. In contrast, when people have more time to decide, don’t face resource pressures, and are making important practical decisions, they are more deliberative and patient. In short, they become wiser.

This generalization has been useful at organizing an often messy literature and has been generative in producing new hypotheses about consumers’ decisions. However, the descriptive adequacy of this perspective has not been thoroughly tested. The papers in this session are all motivated by the same broad question: how do contextual factors affect intertemporal preferences? Each paper investigates a different contextual influence, rethinking and testing the cognitive processes involved in making intertemporal tradeoffs. The novel findings in this set of papers challenge the established wisdom that contextual factors merely shift people from a “fast” system to a “slow” system (and vice versa), and instead reveal richer cognitive processes in intertemporal choice.

The first two papers rethink effects of choice options on impatience. Urminsky and Kim identify diminishing marginal utility as a confound in the prior evidence that people are more impatient for affect-rich goods than cash. In studies designed to correct for or avoid this confound, they demonstrate that in fact people are more patient for goods than money. Hardisty and Weber question the loss aversion explanation for the “sign effect” (more far-sightedness for losses than gains) and find instead that it is better explained by asymmetries in anticipation.

The last two papers rethink the effects of the decision-maker’s situation on impatience. Trueblood and Crane find that limiting deliberative processing through time pressure does not simply make people more impatient. Instead, time pressure makes people less sensitive to information, particularly the length of the delay, resulting in both less and more patience. Likewise, Sharma, Tully and Wang question whether scarcity always leads to short-sighted decisions and demonstrates that a better understanding of people’s needs can predict when scarcity instead leads to decisions favoring the longer-term. Together, these papers point the way to a richer understanding of consumer impatience.

Patient For Candy or Cash?
The Robustness of Impatience Across Affect-Rich and Affect-Poor Resources

EXTENDED ABSTRACT

Research on self-control has long assumed that failures to delay gratification involve affective responses to hedonic options (e.g., Metcalfe & Mischel 1999). This kind of impatience can be understood in terms of temporal discounting. Specifically, the “affective discounting” hypothesis (Vallacher 1993, Loewenstein 1996) suggests that people will be more impatient when making tradeoffs involving more affectively rich outcomes.

Based on this theory, researchers have contrasted people’s discount rates for money and for hedonic goods. Using traditional discounting tasks, in which people choose between less of a resource sooner or more of the resource later, researchers documented a striking empirical regularity: higher discount rates for goods than for money. In over 20 papers, greater impatience has been found for drugs, alcohol, cigarettes, health, food and non-consumable goods (books, DVDs, music, laptops and TVs) than for money (e.g., Sutton and Winer 1993, Tsukayama and Duckworth 2010; see Urminsky and Zauberman 2016 for a review).

These results strongly support the affective discounting hypothesis, suggesting that hedonic rewards lose more subjective value when delayed than do non-hedonic goods or money. However, some research has questioned this conclusion, despite the strong evidence (e.g., Paglieri et al 2015). In particular, Urminsky and Kivetz (2003) find that people are less willing to pay to expedite hedonic goods than practical goods. In four studies, we employ new methods to test the affective discounting hypothesis in general and specifically to test whether people are more impatient for hedonic goods. We first test present bias and long-term discount rates across goods.
In Study 1 (N=670, pre-registered), participants chose between 12 units sooner (of either dollars, candy bars, bags of chips, beer, or new socks, between-subjects) or 16 units of the same good later. Participants chose between now and in a month, as well as between six and seven months (counterbalanced). For all goods, we find significant present bias (greater preference for the later-larger option when both options are delayed; differences between 11% and 22%, all ps<.02). However, there are no significant differences in present bias across the goods, contrary to the assumption that, because hedonic goods lose more value when delayed, they should exhibit more present bias.

In Study 2 (N=849, pre-registered), participants chose between 12 units in six months (of the same goods as Study 1, between-subjects) or 16 units of the good, either in seven months or in one year (counterbalanced). For all goods, we find significant long-term discounting (greater preference for the later-larger when it is delayed by six months than one month). Contrary to the affective discounting hypothesis, however, we observe greater impatience for money (83% vs. 35% waiting, for a 48% difference) than for socks (difference=36%, p < .001), candy bars (35%, p < .001) and beer (29%, p < .001) and directionally greater than chips (39%, NS).

Our results contradict the prior literature, which instead measured discounting by testing how much more of a good would need to be offered in the future, for people to choose to wait. The approach used in the prior literature confounded time preferences with good-specific diminishing marginal utility. In Study 3 (N=249, pre-registered), we measured the subjective utility of different amounts (1, 2, 4, 8, 12 and 16 units) of each good, relative to money. We find that all goods have flatter diminishing marginal utility than money (all ps<.001). For example, 2 candy bars are worth, on average approximately $1.50, but 16 candy bars (8 times as much) are only worth approximately $2.60. This confirms that the higher impatience for goods found in prior research may simply be explained by the fact that additional units of the good are seen as providing little additional value, and therefore serve as poor compensation for waiting.

To test this explanation directly, Study 4 (N=389, pre-registered) extended the methods in Tsukayama and Duckworth 2010 (including socks as an additional good) to enable us to distinguish between present-bias and long-run discounting, and also measured diminishing marginal utility of each good relative to money, as in Study 3. We replicate the findings of Tsukayama and Duckworth 2010, finding greater impatience for all goods than for money. Furthermore, fitting a good-specific quasi-hyperbolic model (Angeletos et al 2001) on the raw data, we find that the effect is driven by a seemingly lower beta (greater present bias) for chips, candy bars and beer than for money (all ps<.001), with beta for socks similar to money. There were no significant differences in long-run discount rate.

However, when we control for the diminishing marginal utility of each good, the results are dramatically different. Modelling the utility of each quantity of goods (rather than the units) we no longer find more present bias for goods than for money, and we find more patient long-run discounting for all four goods than for money (all ps<.001), as in Study 2. This suggests that the prior findings were due to the methods used, which confounded impatience and diminishing marginal utility.

Lastly, in Study 5 (N=402, pre-registered), we replicated the results of Study 4, and also tested an alternative measure of consumer patience, how much monetary compensation people require to delay goods or money. Based on monetary compensation (which avoids the diminishing marginal utility confound in the prior literature) we find greater patience for goods than for money, driven by lower long-run discount rates for goods (all ps<.01), as in Study 2 and 4.

Overall, these findings contradict the affective discounting hypothesis and suggest that people are in fact more willing to wait for goods than for money. Differential impatience across types of goods seems to have less to do with the affective response to hedonic products, and perhaps has more to do with the fungibility and usage rate of a good. These results establish that, when it comes to temptation, cash is king.

The Sign Effect in Consumer Intertemporal Choice: Evidence and Explanation

EXTENDED ABSTRACT

Consumers constantly make choices about what to have now, and what to put off until later. For example, enjoy a paycheck now, or invest it for retirement? Many factors influence preferences regarding the timing of outcomes (Frederick, Loewenstein, & O’Donoghue, 2002; Lynch & Zauberman, 2006). Some of them should apply equally to positives and negatives. For example, the uncertainty that a future event will happen provides as strong of a reason to postpone something negative as to accelerate something positive. Similarly, the interest lost by delaying a $100 reward for a year is equivalent to the interest gained by delaying a $100 loss, and the more that a consumer is connected to their future self, the more they should care about both future gains and future losses (Zhang & Aggarwal, 2015).

Despite these symmetries, laboratory studies typically find that the desire to have good things immediately is much stronger than the desire to postpone negative outcomes (Hardisty & Weber, 2009; Thaler, 1981). Put another way, discount rates for future gains are much higher than discount rates for future losses. Though this “sign” effect has been found with basic “JDM” type SS/LL scenarios, it has been largely ignored in consumer behavior contexts, and the processes driving it are not well understood. Perhaps as a result, the dominant models of consumer choice have largely ignored differences in discounting between positives and negatives. This is a major oversight, given that identical outcomes can be framed as positive or negative events merely by changing the reference point (e.g., energy savings vs energy costs, time gained vs lost).

We test two competing process accounts of the sign effect: loss aversion vs anticipation asymmetry. The loss aversion account is elegant: we know that consumers weigh negative events roughly twice as much as positive events (Baumeister, Bratslavsky, Finkenauer, & Vohs, 2001; Kahneman & Tversky, 1979), and that consumers are more patient for larger magnitude events (Kirby, 1997; Thaler, 1981). Therefore, negative events may be discounted less because they are subjectively larger in magnitude. The elegance and simplicity of this theory has led to its inclusion in several formal models of intertemporal choice (al-Nowaihi & Dhami, 2009; Baucells & Bellezza, 2016; Loewenstein & Prelec, 1992), though it has not been empirically supported.

The second theory, anticipation asymmetry, is one that has perhaps been implicit in research on dread (Berms et al., 2006; Harris, 2010; Story et al., 2013), but has never been explicitly proposed or directly tested as an explanation of the sign effect. According to this theory, the desire to postpone negatives is weaker than the desire to accelerate positives because the (painful) contemplation of future bad things is more intense than the (pleasurable) contemplation of future good things. Thus, while people have a natural impulse to postpone a negative experience (such as paying a bill), the desire to minimize dread pushes in the opposite direction, leading a moderate time preference (i.e., low discount rates for negative events). In contrast, the impulse to receive positive experiences (such as a package in the mail) as soon as possible is barely influenced by anticipatory
feels, resulting in a strong positive time preference (i.e., high discount rates for positive events).

We present three studies demonstrating the effectiveness of the sign effect in consumer decisions, supporting the “anticipation asymmetry” explanation of the sign effect, and clearly disproving the "loss aversion" explanation.

In Study 1, participants (N=200 MTurkers) imagine buying a pair of glasses, and must choose between two different payment plans, which are framed as gains or losses. In the gain frame, they choose between A) pay $122 now or B) pay $142 now, and receive an automatic $30 rebate in one month. In the loss frame, they choose between A) pay $122 now, and automatically pay another $30 in one month, or B) pay $142 now. From a rational economic perspective, the two frames are equivalent (starting with the gain frame and subtracting "$30 in one month" from both options yields the loss frame). Yet, we find that participants choose the “impatient” option A 56% of the time in the gain frame and only 10% of the time in the loss frame, demonstrating the sign effect. We also ran a “small magnitude” condition, where all the dollar amounts were half as large. Comparing the large gain condition (56%) with the small loss condition (8%), we see that the sign effect is equal or even larger after correcting for loss aversion, thus casting doubt on this explanation. We asked participants about their anticipation of the delayed gain or loss, and found that anticipation was more intense for losses than gains, F(1,196)=12.85, p<.01. Furthermore, ratings of anticipation mediated the effect of sign on choices, indirect effect b=.38, SE=.14, CI95 [-.17, .74].

Study 2 was a field study, in which we compared the click-through rate (CTR) of four different advertisements for a retirement calculator on Facebook, using their “AB Testing” feature. Consumers (N=28,568) were randomly assigned to see either a basic positive message (“Starting building your retirement benefits today!” 1.84% CTR), a positive anticipation message (“Looking forward to your retirement benefits?” 2.58% CTR), a basic negative message (“Start building your retirement benefits today!” 2.03% CTR), or a negative anticipation message (“Worried about your retirement expenses?” 3.63% CTR). This negative anticipation condition had a higher CTR than every other condition, all pairwise p<.01.

In Study 3, participants (N=150 students) consumed positive and negative flavored jellybeans in the lab, such as blueberry flavor or dirt flavor. For each participant, we dynamically titrated 20 flavors to find good and bad flavors that were equal in intensity for that person, thus controlling for low aversion. Participants then chose when to eat each jellybean. 63% chose to eat the good flavor immediately, 63% chose to eat the good flavor immediately, whereas only 32% delayed the bad flavor, replicating the sign effect, p<.001. Furthermore, anticipation was stronger for the negative flavor, and anticipation mediated the sign effect, p<.01.

Thinking Fast Does Not Increase Temporal Myopia in Decision-making

EXTENDED ABSTRACT

In intertemporal decision-making, a commonly held hypothesis is that patient choices (i.e., preference for delayed over immediate rewards) require deliberative processing (McClure, Laibson, Loewenstein, & Cohen, 2004) and executive control (Hinson, Jameson, & Whitney, 2003). The key idea is that patience requires effort and time since it relies on overriding automatic impulsiveness. Thus, taxing executive processes and increasing reliance on automatic processes should increase temporal myopia, i.e., impulsiveness. In our studies, we use time pressure to limit executive resources and engage automatic processes. In previous research, time pressure has been used to constrain individuals’ cognitive capacity, to shed light on choice deferral (Dhar & Nowlis 1999), habitual decisions (Wood and Neal 2009) and risky decision-making (Guo, Trueblood, and Diedrich, 2017). Going beyond traditional statistical analysis, we use computational modeling to unpack the cognitive processes that are influenced by time pressure.

In our first study, online participants (N = 101) made binary choices between a small immediate reward (available “now”) and a larger delayed reward. Each participant completed 4 blocks of 30 randomized trials where two blocks involved time pressure (1.5 seconds) and two did not. The time pressure and no time pressure blocks alternated with half of participants randomly assigned to start with the time pressure block. There were 24 main trials constructed by crossing 4 time delays (3, 6, 12, and 24 days) with 6 pairs of monetary amounts ($14 vs. $17, $17 vs. $20, $14 vs. $20, $35 vs. $42.50, $42.50 vs. $50, $35 vs. $50). The remaining 6 trials in each block were catcher trials where the immediate option had the larger reward. The options were displayed to participants using two different formats (varied between subjects): a standard verbal display and a novel perceptual display termed a “calendar grid.” In the perceptual display, options were represented by 4x7 grids where each cell in the grid represented one day with the top left cell representing “now”. We symbolized the monetary values with 6 colors and trained participants to associate colors with their corresponding amount. By using different display formats, we control for the effects of display on decisions, which have been shown to impact behavior (Kwak & Huettel, 2018).

Results from Study 1 showed that as time delay increased (from 3 to 24 days) impulsive (sooner-smaller) choices also increased, consistent with time discounting (F(1,84,167.4) = 33.295, p<.001, η² = .268). In addition, there was a significant interaction between time pressure and time delay (F(3,273) = 13.335, p<.001, η² = .128), where time pressure increased impulsive choices for shorter delays (3-6 days) and decreased impulsive choices for longer delays (12-24 days). These results held for both display formats.

Study 2 (N = 35) was an incentive-compatible laboratory replication of Study 1 where display was a within-subjects condition (all participants completed both displays with 4 verbal and 4 perceptual blocks). The results of this study are consistent with Study 1. As time delay increased impulsive choices also increased (F(1.55,34.1) = 31.611, p<.001, η² = .590). In addition, there was a significant interaction between time pressure and time delay (F(2,284,50.24) = 10.618, p < .001, η² = .326), where time pressure increased impulsive choices for shorter delays and decreased impulsive choices for longer delays.

Our behavioral results suggest time pressure does not universally lead to increased preference for immediate options, contrary to prior accounts. Rather, patience decreased for shorter delays and increased for longer delays. Importantly, these results hold for verbal and perceptual displays and for hypothetical and incentivized choices. To investigate the underlying cognitive mechanisms impacted by time pressure, we used computational modeling to unpack these latent processes. In our model, we assume that decisions are made by sequentially sampling information over time until an internal decision criterion is met. Since the 1960s, this general modeling framework has been successfully applied in almost every area of cognitive psychology including memory (Ratcliff, 1978), perception (Ratcliff, Voskuilen & Teodorescu, 2018), categorization (Nosofsky & Palmeri, 1997), and decision-making (Busemeyer & Townsend, 1993) and has more recently been linked to neural processing in the brain (Gold & Shadlen, 2007). For our purposes, the main component of interest is the internal decision criterion. Through model simulations,
we show the impact of time pressure in our study can be explained by a reduction in the decision threshold. That is, when people are given limited time to decide, they simply use less information (i.e., are less sensitive to delay length) to make decisions. They do not fundamentally change the way they process the information they are given, for example using automatic rather than deliberative processes. The reduction in decision threshold that we observe is a common strategy that people use when making speeded decisions across a range of paradigms from memory to perception (Dutilh et al., 2018).

Our findings help explain how time pressure influences intertemporal choice. Our results show no evidence for increased temporal myopia under time pressure, in contradiction with theories of impulsiveness based on limited executive functioning and automatic processing. Rather, our results are easily explained by a change in people’s decision criterion when forced to make fast choices, a strategy consistent with speeded decision-making in memory and perception.

Scarcity and Intertemporal Choice: An Integrative Framework

EXTENDED ABSTRACT

Most people experience scarcity at some point. Current theories largely purport that scarcity leads to short-sighted decisions (e.g., Haushofer and Fehr 2014; Shah et. al 2012; Tanaka et. al 2010). These theories largely suggest that scarcity reduces attention to and consideration of future consequences. While many studies support this perspective, contradictory findings exist that these theories cannot account for. For example, scarcity has been shown to lead to greater consideration of opportunity costs and greater planning (e.g., Fernbach, Kan, and Lynch 2015; Spiller 2011). Recent research has also questioned the replicability of some of the seminal findings supporting the relationship between scarcity and myopia (Camerer et. al, 2018).

In light of these contradictory findings, we propose a new theory for the effects of scarcity on intertemporal choice. Specifically, we argue that scarcity facilitates a strategic orientation in service of meeting one’s most important need(s), which may or may not be proximal or imminent. Accordingly, we expect scarcity to result in decisions that favor the short-term when, and only when, people believe those decisions are in service of meeting their most important need(s). This perspective allows us to identify when scarcity will not lead to preferences for smaller sooner outcomes, and allows for the novel prediction that scarcity will lead to decisions that favor the longer-term when waiting for later outcomes better enables people to fulfill their most important need(s).

If the effect of scarcity on intertemporal choice is a function of a strategic orientation towards fulfilling one’s most important needs, the effect of scarcity on preferences for smaller, sooner outcomes should depend on whether additional resources are required in the shorter-term. In study 1, participants considered the same need (repaying a car loan) but focused on either a shorter-term (this month’s payment) or longer-term component (repaying the entire loan), and we varied whether participants had sufficient or insufficient resources for this need. The predicted interaction, Wald $\chi^2 = 14.60, p < .001$, showed that when the need was framed as shorter-term, scarcity led to a preference for a smaller, sooner payment option, Wald $\chi^2 = 27.48, p < .001$. However, there was no difference when the need was framed as a longer-term need.

One possibility is that the effects in study 1 occurred because unmet shorter-term needs activate impulsive decision-making. To disentangle this possibility from our proposition, in study 2, we asked participants to consider two needs that varied in importance and the time when resources were needed to fulfill the need. The study followed a 2 (scarce vs. abundant) X 2 (type-of-short-term-need: more vs. less important) design. We found the predicted interaction, Wald $\chi^2 = 5.52, p = .019$. When the shorter-term need was more important, scarcity increased preference for a smaller, sooner payment, Wald $\chi^2 = 10.62, p = .001$. Scarcity had no effect when the shorter-term need was less important, Wald $\chi^2 < 1$.

In study 3, we used natural variation in the unfulfilled needs people deemed most important. The study was run in December, and participants in the scarcity condition wrote about something important they didn’t have enough money for. There were two dependent measures. The first was a choice between completing two online studies. One would occur sooner but would pay less, and the other would occur after New Year’s but pay significantly more. The second dependent measure was an intertemporal choice unrelated to money. After completing these questions, participants in the scarce condition indicated whether getting money before Christmas was necessary in order to meet the need they had written about (binary choice). In line with our pre-registration, participants in the scarcity condition who needed money before Christmas were more likely to choose the sooner study with smaller compensation, Wald’s $\chi^2 = 23.94, p < .001$, whereas participants in the scarcity condition who did not need the money before Christmas were more likely to choose the later study with larger compensation, Wald’s $\chi^2 = 6.70, p = .010$. There were no differences for the non-monetary dependent measure.

In study 3, one possibility is that the measure capturing need-for-money-later simply captured general time preference. Thus, in study 4, we manipulated scarcity across all participants but varied whether the dependent measure was relevant to the threatened need. All participants listed an important need they had insufficient resources for, but we varied whether that resource was money or time. Then, participants completed an incentive-compatible monetary titration task in which they chose between $30 now or a larger amount 45 days later. Next, participants indicated the extent to which they needed additional resources (money or time) within the next 45 days to meet the need they had written about. We found the predicted interaction, $t(413) = -3.81, p < .001$. Among participants who needed resources in the shorter-term, those facing monetary (vs. time) scarcity preferred the smaller, sooner amount of money; however, among those needing resources in the longer-term, those facing monetary (vs. time) scarcity preferred the larger, later amount of money.

In study 5, we examined a common situation in which people experience scarcity due to a future expense: a wedding. We posted ads for the study on Facebook, targeting individuals who were recently engaged. We offered a lottery to win money in exchange for completing the study. Participants reflected on aspects of their upcoming wedding, focusing either on what they were most concerned about being able to afford (scarcity condition) or what they were most excited about (control condition). Then, participants chose whether they would prefer getting the advertised lottery amount now, or a larger amount in three months. As predicted, those in the scarcity (vs. control) condition were more likely to choose the larger, later amount, Wald $\chi^2 = 4.23, p = .040$.

In sum, these results provide a more accurate understanding of why and when scarcity influences intertemporal choices. Our theory suggests that the relationship between scarcity and intertemporal choice is better explained in terms of a strategic orientation towards fulfilling one’s most important needs (vs. impulsivity or lack of consideration of the future).

ADVANCES IN CONSUMER RESEARCH (VOLUME 47) / 313

SESSION OVERVIEW

We may be living in a “postcolonial world,” but the vestiges of colonialism live on—often mediated by markets and reproduced through marketing practices. In this special session, we trace the trajectories of past marketing practices and cultural forces into the present to understand opportunities and obstacles for consumer empowerment through marketplace decolonization. Decolonization represents decoupling from the structures and practices of colonialism (Mignolo 2007).

This session addresses two questions: 1) How do marketing practices reinforce institutionalized representations of colonized people as exotic and disempowered others? 2) How can shifts in macro-market understandings of colonized people impact how they are represented and their opportunities in the marketplace? This session explores colonized people as consumers and producers, as targets of cultural appropriation, and as powerful culture-makers. These four presentations converge on the social construction of colonized people through marketplace practices and structures—seeking to understand opportunities for agency and identify alternative trajectories. These presentations focus on how cultural moments can provide opportunities that empower colonized consumers (e.g., Roma people) and producers (e.g., Australian Aboriginal artists) with the agency to resist and decouple from post-colonized markets. The first two presentations investigate how colonial institutions are reproduced through advertising and continue to haunt cultural branding practices. First, Veresiu shows how the framing of colonized subjects as “exotic others” continues in contemporary marketing practices. Veresiu explores resistance by Roma consumer activists towards the Knorr Gypsy Sauce branding, revealing strategies of justification enacted by marketers to legitimate interlacing colonial logics and racialized representations in cultural branding. Second, Varman analyses historical advertising to understand representations of colonized Indian people. Varman illustrates colonial agendas of disempowerment and enslavement underpinning advertising imagery of those times. Varman highlights the vestiges of colonialism and “epidermal schema”—logics based on skin color—that remain at the fringes of marketing practice.

The next two presentations focus on the Australian Aboriginal art market to investigate how markets represent colonized people as producers of culture, and how these representations are influenced by macro-level cultural changes. Rentschler and Belk analyze the appropriation and representation of Aboriginal Art by a formal institution—the Australian Council for the Arts. They examine how representations of Aboriginal art and artists by powerful institutions shift to mirror social changes in broader Australian culture. Chow et al. develop this thread to show how shifting cultural sensibilities and formalized legislation enable Aboriginal artists to fill positions of legitimacy, take control of their marketplace representation, and use the market to their own ends. They explain how producer resistance and market decolonization is possible.

These four presentations employ a range of methods including the analysis of textual and visual archival data, participant observation, and in-depth interviews. They draw on different post-colonial theories including Fanon’s (1961) theory of decolonization, Boltanski and Thévenot’s (1999) theory of justification, fugitive theory of decolonization (Martineau and Ritskes 2014; Mignolo 2007, 2009). This session will be interesting to researchers seeking in-depth understandings of the impact of colonization on consumers and producers of culture, and to explore avenues for positive change.
of worth” (1991, 15): civic, market, industrial, domestic, inspiration, and fame. The scholars (Boltanski and Thévenot 1991) further argue that these justifications conflict with one another as individuals compete to legitimize their own opinions over others. In other words, “in contested institutional environments, […] focal organizations and other stakeholders have to engage in continuous work of justification across available orders of worth, in order to maintain an acceptable level of legitimacy for their actions” (Patriotta et al. 2011, 1806). Building on Boltanski and Thévenot’s (1991) justification theory, I argue that cultural branding represents a contested institutional environment where activist consumers initiate a critical moment that sets in motion a series of justifications. However, it remains theoretically unknown and empirically unverified which justification logics apply in the cultural branding realm.

Hence, to empirically investigate the racialized cultural branding phenomenon, I focus on the market-based battle between minority-group activist consumers and dominant-group Unilever brand managers in Germany over the popular Knorr Gypsy Sauce. Methodologically, I collected archival media data consisting of German online and in-print coverage of the controversial Gypsy sauce topic, which uses a racist term for an ethno-race known as Roma, as well as semi-structured interviews with Roma consumers and Unilever employees. A hermeneutical approach (Thompson 1997) was used to analyze the complete data set. To provide context, the Roma are a traditionally nomadic, clan-based people who travelled from India across Europe during the Middle Ages (Belton 2005). Currently there are between 170,000 to 300,000 transnational individuals who reluctantly self-identify as the two main clans (Roma or Sinti) in Germany, especially since up to 1.5 million were murdered during National Socialism (Minority Rights Group International 2018). Today, the Roma/Sinti continue to be disparagingly referred to as “Zigeuner” (meaning Gypsy in the German language) by the indigenous German population. Furthermore, the tomato-based “Zigeunersauce” (Gypsy sauce) persists as a staple in mainstream German cookbooks, restaurants, and supermarket shelves from iconic food brands including Heinz, Kühne, and Knorr.

My analysis reveals that Roma/Sinti activist consumers relied exclusively on the civic order with its focus on collective welfare, equality, and solidarity (Boltanski and Thévenot 1991) to publically justify renaming Zigeunersauce to paprika or spicy sauce due to its racist connotation. In response, Unilever employees mobilized all five of the remaining logics to publically justify keeping the original name of Zigeunersauce. These institutional informants first combined the market and industrial orders in what I refer to as an economizing strategy by discussing increased costs and market statistics associated with such a large-scale product rename. Next, they utilized the inspired order through emotional appeals, which I refer to as a romanticizing strategy. This was followed by a historicizing strategy using the domestic order by focusing on the sauce’s heritage. Lastly, they resorted to the fame order by discussing brand recall and recognition, which I call a consumerizing strategy. Together the four strategies identified form a process of myth market justification used to depoliticize Knorr’s Zigeunersauce racially charged cultural branding meanings. More importantly, a key takeaway relating to consumer empowerment is for brand activists to engage more than one order of worth when fighting for market change. Hence, future research should systematically compare different racialized brands across the world, especially focusing on successful cases to examine which orders of worth lead to changing the racialized cultural branding landscape.

Colonial Advertising, Desubjectification, and Epidermalization of Servitude in India

EXTENDED ABSTRACT

While much of consumer research has attended to how consuming subjects are constituted by advertising, little attention is paid to how commercial representations further colonial discourses and desubjectify vast populations in the Global South. In an historical analysis of advertising in colonial India from 1869 to 1940, I offer insights into how commercial representations were steeped in the recurrent violence of colonization and enslavement. As my data source, I used the archives of The Times of India, a leading English daily before and after India’s independence in 1947. The newspaper started as The Bombay Times and Journal of Commerce in 1838 and became The Times of India in 1861. It was owned by British businessmen until 1946, when it was sold to an Indian businessman.

Drawing upon the work of Frantz Fanon (1952), I attend to the ontology of the colonized in which the colonizer’s gaze constituted Indians as objects. This colonizer’s gaze robbed Indians of their agency and lived experiences, and located any notion of being in relation to the subject positions occupied by the colonial masters. In contrast, as a form of ontological resistance, through advertising the colonized could not do the same to their White masters. In these representations, I draw attention to how, on the one hand, it was popular to show Britishers as consumers of various goods. On the other hand, Indians were mostly marked by their absence as consumers, and their political struggles for freedom were in a state of eclipse in these advertisements. In particular, at the peak of political movements such as the Non-Cooperation Movement (1920-1922) and the Civil Disobedience Movement (1930-1934), the lived experiences and struggles of the colonized Indians found almost no representation in advertising by British businesses. While the colonial society in the early 20th century was witnessing popular uprisings, the colonized and their emotional worlds were eschewed to maintain the purity of Whiteness in advertising. This failure to afford the weight of intentionality to the emotions of the colonized was affective violence and became an important structural condition of their oppression because it allowed exploitative transfer of the burden of negative affect onto the enslaved. Fanon (1952, 92) refers to this phenomenon as “affective tetanization,” through which the colonized became a site of mass projection or collective catharsis for the colonizer and Indian bodies were marked as phobic objects, associated with taboos, the horror of unclean things, and polluting influence that were to be kept away in these commercial representations. Despite the desire of the colonized, as Fanon (1952, 92) reminds us, to be a “man, and nothing but a man,” and their rejection of affective tetanization, they were denied recognition as consuming subjects in advertisements. Fanon sees this as a feature of an affective economy of colonialism that requires a site of projection in the process of subject formation. It also means that such presence and absence in colonial advertising echo Fanon’s observation that colonialism was not just a system of creation of inferior subjects but also of desubjectification.

Furthermore, in a few advertisements in which Indians were depicted, they were either confined to the background or shown as servants of their White masters. These unequal commercial representations draw attention to Fanon’s idea of historicity in which the colonized are caught in an infernal circle wherein the past overwhelms the present at the expense of movement toward a future that might be different from the past. The colonized are determined by the racial-epidermal schema of their stigmatized race. As Fanon (1952, 92) insightfully notes, “the bodily schema, attacked in several places, collapsed giving way to an epidermal racial schema.” Here,
Fanon offers a corrective to Merleau-Ponty's (2012) reading of intentionality through bodily schema in which the whole body, with all its sensory, motor, and affective operations, is that through which the world appears. The bodily schema is altered by a racial-epidermal schema because the colonized are forced to see themselves through the colonizers’ eyes and their narratives, as Fanon (1952, 95) observes, “I am over-determined from outside….The White gaze the only valid one, is already dissecting me, I am fixed.” In colonial advertising, the appearance of Indians in positions of servitude and their disappearance as consumers are racially coded and ossified in their skin colors. As a result, the colonized’s bodily schema is subtended by a racial-epidermal schema.

Summing up, my postcolonial reading of advertising further consumer research by drawing attention to colonization, servitude, and racial-epidermal schema that remain at the margins of the discipline. Such a reading is particularly necessary because the colonial mode of representation still asserts itself as a natural expression of existing socio-economic relations in postcolonial societies, even though the specific political system characterized by European colonial rule has been defeated.

‘I am the Old and the New’: The Place of Aboriginal Art in the Australian Art World, 1973-2018

EXTENDED ABSTRACT

This study presents an analysis of the changes in the presentation of images of Australian Aboriginal and Torres Strait Islander (Aboriginal) art and artists in the Australia Council for the Arts annual reports from 1973 until 2018. We also draw on interviews and observations to examine how these images articulate changing understandings of Aboriginal peoples and culture as Australia began to embrace multiculturalism, postcolonialism, and the rights of indigenous Australians. We ask whether these changing images correspond to transforming program content by this preeminent arts council or whether the images have been appropriated without adequate compensation -- acting perhaps as a metaphor for the historical appropriation of Australia by non-Aboriginal settlers and immigrants over the past several hundred years. The historic pattern of images is considered against the wider transformation of Australian culture at dramatic key points of Aboriginal political protest in the wider community. Surprisingly, the annual reports are generally silent about protestations and instead make efforts to demonstrate self-determination among marginalized Aboriginal peoples. Our findings challenge expectations about images of art, artists, and of people in artistic leadership roles, revealing the complexity of factors shaping Australian art worlds during a 45-year period in which cultural values regarding Aboriginal people changed dramatically.

Starting in the last quarter of the twentieth century, there has been a major shift in Australian regard for the history and culture of its original and current Aboriginal inhabitants. It was only with the 1992 Eddie Mabo court decision that Australia overturned the doctrine of terra nullius – the legal fiction that Australia was uninhabited when European explorers and settlers arrived. Among the changes that occurred was the explosion of global interest in Australian Aboriginal art, as signaled for example by the inclusion of art by Rover Thomas and Trevor Nickols in the 1990 Venice Biennale (Belk and Groves 1999). We ask: “how has art ethnicity been presented over the past 45 years in the annual reports of Australia’s national arts council?” More specifically, we ask whether the representation of Aboriginal and non-Aboriginal art became less colonial and primitivist and more contemporary; that is, have new images of art, artists and artistic leadership emerged in the representations of images on the covers and interiors of annual reports? We also examine whether the financial support of the Australia Council for the Arts (ACA) for Aboriginal art has kept pace with the growing direct and indirect importance of Australian Aboriginal art in driving international tourism to the country as well as enriching the image of the country abroad.

We employ a qualitative semiotic analysis of images from its annual reports. In addition to this large data base, the analysis draws on interviews with key Aboriginal and non-Aboriginal members and directors of the ACA over this period. This allows us to assess the extent to which the image representations have changed over the 45 years, during which new Aboriginal art forms emerged and became recognized as ‘high art’ rather than ‘anthropological objects.’

This study makes three contributions. First, given their potential for influence on national cultural policy, arts councils and their annual reports offer insight into evolving regard for Aboriginal Australians and Aboriginal art. Second, our study recognizes that arts councils play a key role in classifying culture. For this reason, arts council annual reports enable the analysis of long-term trends in categories of art and artists. For example, a given artist, might well wish to have her work recognized as “contemporary art” rather than “urban Aboriginal art.” Third, prior studies have shown that the arts act as a means of ‘soft’ diplomacy and offer a way for a country to create its identity and place in the world. Images form an important part of identity creation but have been little studied within this domain. Images appear in a variety of cultural contexts in annual reports. We examine their focus on art, artists and artistic leadership. Images are narrative tools that tell stories; stories are a key means of conveying meaning in culture. While we find a growing tendency to represent Aboriginal art as sophisticated rather than as a primitive anthropological curiosity and to recognize the importance and rights of Aboriginal people over the 45 years studied, we also find a shrinking tendency to fund Aboriginal art at a level commensurate with its importance to Australian culture and economy. Thus, we conclude that neocolonialist marginalization and exploitation continue.

The Indigenous Art Market: A Site of Cultural Production or Cultural Assimilation?

EXTENDED ABSTRACT

Please be aware that this publication/resource may contain the names of Aboriginal and Torres Strait Islander people who may now be deceased.

First Nations people in Australia, Asia, the Americas, and Europe have long been affected by colonization practises of cultural assimilation into non-Indigenous cultures and even cultural annihilation. In Australia, many Indigenous people continue to struggle under contemporary forms of colonialism that deny their rights to ownership of ancestral lands and equitable access to health, education, and employment (Australian Institute of Health and Welfare 2015; Watson 2009).

Against this backdrop of historical and contemporary colonialism, this presentation explores how Indigenous artists use their art to

---

1 One of the Aboriginal interviewees used these words. They reflect (i) knowledge of the retrospective exhibition of Aboriginal artist, John Mawurndjul, at the Art Gallery of South Australia, October 2018-January 2019 as part of the Tarnanthi Aboriginal arts festival, and (ii) her knowledge of the place of history and tradition for Aboriginal peoples being balanced against living in contemporary society as an urban Aboriginal person.
create and re-create Indigenous culture both for their own communities and the larger art market. Martineau and Ritskes (2014, I) argue, “[a]gainst colonial erasure, Indigenous art marks the space of a returned and enduring presence.” In Figure 1, Indigenous artist Mumu Mike Williams produces art to celebrate his culture. He also sends a powerful statement about Indigenous land ownership in the APY Lands in central Australia. In describing his artwork, which was painted “illegally” on canvas Australia Post mailbags, he explains: “Pamputja Wiya: that means don’t touch! Don’t touch Rockhole, don’t touch our dreaming. I’m talking to politicians, to the government (Moodie 2017).”

In light of the resistive production practices of Indigenous culture-makers such as Mumu Mike Williams, we investigate the Indigenous art market as a site of cultural production and decolonization. The study is informed by postcolonial and decolonization theories that encourage the exploration of tensions between Western research and Indigenous knowledge systems (e.g., Denzin, Lincoln, and Smith 2008; Tuhiuwi Smith 2012). While postcolonial theorists (e.g., Bhabha 1994; Said 1978; Spivak 1999) call for an analysis of cultural and epistemic legacies of colonialism, decolonization is an expression of “epistemic disobedience” (Mignolo 2009, 15) and de-linking from colonial thought (Mignolo 2007). Decolonization requires “re-center[ing] Indigenous land, communities and cultures” (Martineau and Ritskes 2014, II) to provide fugitive possibilities for cultural production and creative expression. Thus, this study asks: How do Indigenous artists and art intermediaries break away from the colonialism’s enforced silence and revitalize fugitive Indigenous cultures through the market?

We draw on interviews with art mediators and influencers, participant observation at art exhibits, as well as an historical analysis of archival data of the Australian Indigenous art market. We analyze our data through the conceptual lens of decolonization to theorise Indigenous peoples’ collective struggles for freedom, empowerment, and cultural resurgence.

While past marketing studies explore the dynamics of the art markets in the USA and China (Joy and Sherry 2003, 2004), this study focuses on the Australian Indigenous art market and conceptualizes the marketplace as a fugitive space where Indigenous artists and intermediaries reassert the power of their Indigenous cultures and knowledges against colonial forces and structures. As Métis, Canada’s First Nations People’s activist, Mederic McDougall pointedly states, “We do not want to be integrated into a decaying white society. Why enter a house that is burning down?” (cited in Adams 1999, 74). Thus, we extend current understanding of the art market, conceptualizing it as a site with the potential to inspire and sustain Indigenous people’s collective struggles for freedom, empowerment, and cultural resurgence.

Paper #4: Inspirational Aesthetics: How Beautiful Products Motivate Performance
Kelly Herd, University of Connecticut, USA
Page Moreau, University of Wisconsin, USA

SESSION OVERVIEW
“Beauty is in the eye of the beholder.” Abundant research has shown that physically attractive individuals are perceived as having more socially desirable attributes (Eagly et al. 1991; Langlois et al. 2000) and gain many benefits from these positive evaluations, such as better jobs and higher wages (Hamermesh and Biddle 1994). These benefits are known as the “beauty premium” and motivate people to engage in beauty practices (i.e., applying cosmetics) to enhance their physical attractiveness. However, the degree to which the beauty premium generalizes to various consumption contexts is yet unclear and many questions remain about the factors and underlying mechanisms associated with consumption of beauty-related products. This session provides new, vital perspectives in this domain.

The first two papers explore boundary conditions on the beauty premium in two different consumption contexts: service failure and micro-lending. First, Wan and Wyer focus on the impact of service providers’ physical attractiveness on consumers’ reactions to a service failure. They show that consumers are less forgiving of an attractive (vs. average-looking) opposite-sex provider’s social service failure, and this pattern is more pronounced for communal (vs. agentic) participants. However, consumers are more forgiving of an attractive (vs. average-looking) opposite-sex provider’s non-social service failure. This effect is driven by social competence expectation violation. Next, Mesler, Besharat, and Argo shift to a micro-lending context and examine how consumers’ own physical attractiveness and lenders’ physical attractiveness interactively impact the amount lenders are willing to grant. Results suggest that unattractive (vs. attractive) lenders assign lower creditworthiness to attractive (vs. unattractive) borrowers and subsequently lend them less. Notably, this effect is mitigated when the borrowers’ credit is tarnished or when the lenders are self-affirmed.

Despite the fact that beauty can lead to negative consequences, as documented above, consumers still invest great efforts into enhancing their physical attractiveness, even in virtual environments. The third paper by Wang, Morales, and Samper examines when and why consumers use photo-editing beauty apps to make themselves look more attractive in photos. They find that interdependent (vs. independent) consumers have higher intentions to use beauty apps when seeing both the unedited and beautified photos side-by-side, because they see greater overlap between their beautified and true selves, just as they see greater overlap between themselves and other people. However, this effect is mitigated when consumers only see the beautified photo in isolation, as the discrepancy in appearance is less apparent.

Finally, Herd and Moreau conclude by exploring whether the beauty premium also applies to beautiful products. Specifically, they show that using beautiful products increases consumers’ self-efficacy via an assimilation mechanism, which subsequently translates into greater motivation and better actual performance while using the product. They also show that the effect holds only when an upward comparison target is absent (vs. present).

Collectively, these four papers provide new perspectives on the role of beauty in consumer decision making. Each paper includes a complete set of experiments and provides process evidence that can stimulate new research ideas and practical insights in the domain of beautiful people and products.

When a Beautiful Service Provider Makes Mistakes: To Forgive or Not to Forgive?

EXTENDED ABSTRACT

Attractive service providers of the opposite sex typically elicit favorable consumer reactions (e.g., Ahearne, Gruen, and Jarvis 1999; Argo Dahl, and Morales 2008; Wan and Wyer 2015). In some cases, however, the physical attractiveness of service providers might decrease the favorableness of consumers’ reactions to them. Because attractive service providers are attributed social competence (Eagly et al. 1991), they are expected to be particularly capable of delivering good service. Therefore, when this expectation is violated, consumers might relatively less forgiving of their mistakes.

Previous research (e.g., Chan, Wan, and Sin 2009; Grönroos 1984) has distinguished between nonsocial and social failures. A non-social failure results from the provider’s incompetence (e.g., the waiter took the wrong order) but a social failure involves a violation of expectations surrounding an interaction with a provider (e.g., the waiter is impolite), independently of the provider’s competence. Therefore, consumers may react less positively to a provider’s social failure, but more positively to a provider’s nonsocial failure, if the provider is attractive than if (s)he is less attractive.

We also suggest that agency-communion orientation would further moderate the relationship between physically attractiveness and consumer reactions to service failures. An agentic orientation refers to an individual’s tendency to emphasize the self and its separation from others, whereas a communal orientation refers an individual’s tendency to focus on social relations (Helgeson 1994). These differences can either be chronic or induced experimentally (Kurt, Inman, and Argo 2011), for example, males are perceived to be agentic-oriented and females are perceived to be communal-oriented. Because communal (vs. agentic) consumers are more sensitive to interpersonal interactions, their reactions to attractive and less attractive providers’ mistakes might be particularly pronounced.

Four experiments confirmed these predictions. In a pilot study, males (n = 180) participated in a study of first impressions. They re-
ported higher expectations that opposite-sex service providers would be socially competent when they were physically attractive than when they were average looking (8.27 vs. 7.24, respectively; \(F(1, 176) = 35.22, p < .001\)). No difference was found in perceptions of a same-sex provider’s competence, however (7.18 vs. 7.04, respectively; \(F(1, 176) = 1.36, p > .10\)).

In experiment 1, female participants (n = 128) were invited to be a mystery shopper and to visit a company’s booth that was set up at their University. They were randomly assigned to cells of a 2 (salesperson attractiveness: high vs. average) \(\times\) 2 (service failure type: social vs. non-social) between-subjects design. Each participant, run individually, arrived at a room that simulated a retail booth in a particular time slot. Two male confederates (age = 22) with different levels of physical attractiveness were recruited to be the salesperson. In non-social failure conditions, the salesperson was instructed to perform ineffectively. In social failure conditions, the salesperson was trained to give limited eye contact, did not smile, and looked unfriendly during the interaction with participants. Analyses of dissatisfaction yielded an interaction of service failure type and attractiveness (\(F(1, 124) = 26.68, p < .001\)). In nonsocial failure conditions, participants were less dissatisfied if the salesperson was attractive than if he was average looking (5.63 and 6.81, respectively; \(F(1, 124) = 31.46, p < .001\)). In social failure conditions, however, the pattern reversed (7.95 and 6.94, respectively; \(F(1, 124) = 23.23, p < .001\)). Mediation analysis confirmed (Model 8, Hayes 2013) that the interactive effects of attractiveness and service failure type on dissatisfaction were mediated by their effects on social competence expectation violation (based on 5000 samples, 95% CI ranged from .0802 to 1.1710).

Experiment 2 examined the moderating role of agency-communion orientation and used gender as a proxy for the agency-communion orientation. Two hundred eighty-eight participants (50% males) were randomly assigned to conditions of a 2 (service provider attractiveness: high vs. average) \(\times\) 2 (orientation: agency vs. communion) \(\times\) 2 (service failure type: social vs. non-social) between-subjects design. They imagined themselves shopping for a smartwatch. In non-social failure conditions, they imagined requesting a specific smartwatch with a fitness tracker and GPS function, but the salesperson gave them a watch of the wrong color and no GPS. In social failure conditions, participants imagined that the salesperson did not smile to them and gave them limited eye contact when they made the same request. As predicted, the three-way interaction involving agency-communion orientation, service failure type and attractiveness was significant (\(F(1, 280) = 5.39, p < .05, \eta_p^2 = .02\)). This interaction is attributable to the fact that the effect of physical attractiveness under the nonsocial failure and social failure was more pronounced for communal participants (\(M_{att} = 1.64\) vs. -1.14, respectively; \(F(1, 280) = 41.48, p < .001\)) than for agentic participants (\(M_{att} = 0.61\) vs. -0.75, respectively; \(F(1, 280) = 9.93, p < .01\)). Put another way, the interactive effects of physical attractiveness and agency-communion orientation were restricted to social failure conditions (\(F(1, 280) = 10.01, p < .01\)). The corresponding interaction in the non-social failure conditions was not reliable (\(F < 1\)).

Experiment 3 (n = 304) used a scrambled-sentence task as a priming task to induce differences in agency-communion orientation (Kurt, et al. 2011) and it replicated the findings of experiment 2. It also confirmed the mediating influence (Model 12, Hayes 2013) of social competence expectation violations on the interactive effects of attractiveness, service failure type, and agency-communion orientation on dissatisfaction (based on 5000 bootstrapping samples, the 95% CI ranged from .1289 to 1.0501).

The present research demonstrates that although consumers react more positively to attractive (vs. average looking) opposite-sex service providers when they commit a non-social failure, they react more negatively to them when they violate expectations for social competence. This pattern is stronger for consumers with a communal (vs. agentic) orientation. It is the first to identify conditions in which the physical attractiveness of a service provider can decrease the favorableness of consumers’ reactions to the provider rather than increasing it in service failures. These findings offer valuable managerial insights into the role of service providers’ physical attractiveness on consumers’ behavior.

**Creditworthiness is in the Eye of the Beholder: How Consumers’ Own Attractiveness Shapes Generosity toward [Un]Attractive Microloan Borrowers**

**EXTENDED ABSTRACT**

When your only hope for business funding is a loan from strangers, is being beautiful better? Although attractive individuals are ascribed more positive attributes (Eagly et al. 1991) and outcomes (Antonakis and Dalgas 2009), boundary conditions on this beauty-is-good effect are emerging (Argo and Dahl 2018). Herein, five experiments demonstrate that lenders’ own attractiveness moderates the effect of a microloan recipient’s attractiveness on lending.

First, we show that lenders who self-report as (study 1a), are rated by others as (study 1b), or are manipulated to feel (study 1c) less attractive derogate an attractive borrower through their creditworthiness, and in turn lend less. Study 2 examines this implicit threat mitigation by manipulating borrower creditworthiness; unattractive lenders become more generous toward attractive borrowers when the threat of a borrowers’ attractiveness is mitigated by low credit. Finally, when unattractive consumers’ threat is mitigated through self-affirmation (study 3), their generosity toward attractive borrowers is enhanced.

**Studies 1a-1c.**

Studies 1a-1c utilize a borrower attractiveness (high vs. low vs. control, study 1a; high vs. low in studies 1b and 1c) by lender attractiveness (self-reported, study 1a; other-rated, study 1b, and manipulated via false positive/negative feedback, study 1c) designs among MTurkers (n=219 in study 1a; n=346 in study 1c) and undergraduates (n=457, study 1b). All participants were provided with an overview of microlending followed by an advertisement featuring a borrower, then rated the creditworthiness of that borrower (3 items; alpha=.91), then indicated the percentage of their payment (studies 1a, 1c) or dollars (study 1b) they would lend. In study 1c, participants also completed situational self-esteem (from Rosenberg 1965). Finally, respondents completed a manipulation check and demographics.

**Study 1a Results**

Using PROCESS model 9 (Hayes 2018), the borrower attractiveness and lender attractiveness interaction predicting creditworthiness was significant (\(b=.27; t(1,213)=2.66, p<.05\)); creditworthiness also predicted payment (\(b=.56; t(1,213)=6.59, p < .001\)). Among attractive borrowers, creditworthiness significantly mediated the relation between lender attractiveness and amount loaned (\(b=5.19; CI=1.88\) to 11.04). However, the impact of lender attractiveness on loaned amount through creditworthiness became non-significant when the borrower was unattractive (\(b=1.34; CI=-.76\) to 3.02). Thus, consumer lending behavior is subject to the borrower’s attractiveness and the lender’s self-reported attractiveness. Unattractive lenders responded to attractive borrowers by evaluating them as less creditworthy, and in turn lending less money. However, attractive lenders...
did not differ in their creditworthiness assessment and subsequent generosity toward any borrower, irrespective of their attractiveness.

Study 1b Results
Using model 7, we find a significant interaction between borrower attractiveness and lender objective attractiveness on creditworthiness \((b=.79; t(1,225)=3.99, p<.001)\), and creditworthiness also predicted payment \((b=7.98; t(1,226)=3.39, p<.001)\). When the borrower is attractive, creditworthiness significantly mediated the relationship between lender objective attractiveness on the amount loaned \((b=6.39; CI=[2.41 to 12.36])\) but not when the borrower was unattractive \((b=10; CI=[-2.52 to 2.37])\). Importantly, the use of other-rated attractiveness suggests the threat effect observed is not due to self-esteem; however, this is further ruled out in study 1c.

Study 1c Results
Again using PROCESS model 7, the interaction of borrower attractiveness and lender attractiveness predicting creditworthiness was significant \((t(1,359)=-2.31, p=.02)\), and creditworthiness also significantly predicted lending behavior \((t(1,359)=3.27, p<.001)\). The pathway from lender attractiveness to payment lent through creditworthiness did not include zero for unattractive borrowers \((CI=[.07 to 1.94])\), or attractive borrowers \((CI=[-.486 to -.06])\). Consumers who were primed to feel unattractive assigned lower (higher) creditworthiness to attractive (unattractive) borrowers, which in turn reduced the amount of money they were willing to lend. In contrast, self-esteem did not mediate the moderation effect \((PROCESS model 7; CI=[-.37 to 1.19])\). Next study provides further evidence of the underlying mechanism by manipulating borrower creditworthiness.

Study 2
MTurkers \((n=201)\) participated in a 2(Borrower Attractiveness: attractive vs. unattractive) x 2(Borrower Creditworthiness: low [2-star] vs. high [5-star]) between-subjects design within lenders who were primed to feel unattractive. We used the false photo-feedback manipulation and data collection procedure used in study 1c. Using model 1, the interaction between creditworthiness and borrower attractiveness on lending was significant \((t(1,197)=2.37, p<.05)\). Under high creditworthiness, attractive borrowers received significantly less money from unattractive lenders than did unattractive borrowers \((F(1,197)=8.37, p<.05)\). However, this difference disappeared under low borrower creditworthiness \((F(1,197)=.34, p>.05)\). Thus, highlighting creditworthiness advantaged attractive borrowers \((b=.79; t(1,225)=3.99, p<.001)\), and improving creditworthiness of the attractive borrowers with lower credit. In study 3, we assess a second way to mitigate the threat posed by attractive borrowers, by utilizing an affirmation task.

Study 3
Prolific Academic panelists \((n=177)\) participated in a 2(Borrower Attractiveness: Attractive vs. Unattractive) x 2(Lender Self-Affirmation: Yes vs. No) between-subjects design within unattractively primed lenders. Participants were randomly assigned to receive either a self-affirmation or a filler task (White, Simpson and Argo 2014). Participants then viewed an ad containing either an attractive or unattractive borrower (Gonzalez and Loureiro 2014). Finally, participants indicated the percentage of their compensation they would lend. Model 1 revealed a significant interaction between borrower attractiveness and self-affirmation \((t(1,173)=2.42, p<.05)\). In the no-affirmation condition, unattractive lenders were again significantly less likely to lend money to the attractive \((b=.98, CI=[.82 to 1.14])\), unattractive lenders did not differ in lending to the attractive \((b<.05)\) when they received an affirmation \((F(1,173)=.13, p>.05)\). Thus, threat management was mitigated when an unattractive lender was given a self-affirmation.

Discussion. Across 5 studies, while being more attractive is better in achieving funding, this effect depends on the attractiveness of the lender. Less attractive consumers loaned significantly less to attractive borrowers after attenuating borrower creditworthiness appraisals \((studies 1a-1c)\). When this implicit threat was mitigated by tarnishing the borrower’s credit \((study 2)\) or affirming the unattractive lender \((study 3)\), generosity to an attractive borrower was heightened. We add to the literature on attractiveness, finding that even individuals a world away and in need of help can initiate a substantive threat response in consumers. As half of all consumers are below the mean on attractiveness, and conventional wisdom suggests the importance of “looking your best”, our findings are also instructive for microloan borrowers, administrators and platforms.

The Beautified Me is Me: How Interdependence Increases Beauty App Use Intention

EXTENDED ABSTRACT
In the digital age, the availability of powerful, simple-to-use photo-editing apps, such as Beauty Plus and Facetune, means that the creation of visually compelling photographs is growing at an incredible speed (Nightingale, Wade, and Watson 2017). These tools provide consumers with a myriad of options, such as removing wrinkles and reshaping the face, to make themselves look better than they really do. Previous research has shown consumers desire to project true and authentic selves (Sheldon et al. 1997; Wood et al. 2008). However, the increasing number of manipulated photographs on social media reveals that many consumers also choose to present less authentic or even “fake” selves (Nightingale et al. 2017). This research tries to address why consumers use beauty apps to enhance their physical attractiveness in photos and which consumers are more likely to do so.

Across five studies, we demonstrate that consumers’ intentions to use beauty apps depend on the overlap they see between their ideal (beautified) and true selves, which is influenced by how they construe their sense of self and the evaluation mode they are in when they see the photos. Specifically, when in a joint evaluation mode (i.e., consumers see both the unedited and beautified photos side-by-side), interdependents (vs. independents) tend to see greater overlap between their beautified and true selves, just as they see greater overlap between themselves and other people, and thus have higher intentions to use beauty apps to edit their photographs. However, interdependents (vs. independents) are equally likely to use beauty apps when in a separate evaluation mode (i.e., only see the beautified photo).

Experiment 1 provides initial evidence that interdependents (vs. independents) have higher intentions to use beauty apps when in a joint evaluation mode. We first primed self-construal using a writing task about similarities with or differences from close friends and families (Lalwani and Shavitt 2009). Afterwards, participants read an ad for a beauty app with both an unedited face and a beautified face of the same model, which is similar to most of the real beauty app ads. Then participants rated their app use intention and the overlap between their beautified and true selves if they used the app to beautify their selfie. A one-way ANOVA on the beauty app use intention indicated that participants primed with interdependence were marginally more willing to use the app than those primed with independence \((F(1,144)=3.75, p=.055)\). The same effect was found for self-overlap \((F(1,144)=4.38, p<.05)\). Mediation analysis (Model 4, Hayes 2013) indicated that self-overlap mediated the effect of...
self-construal on beauty app use intention (CI: 0.0298, 0.9341). The greater overlap consumers see between their beautified and the true selves, the higher intentions they have to use beauty apps.

Experiment 2 further tested the effect by measuring self-construal (Singelis 1994) and showed that the effect was mitigated when consumers were in a separate evaluation mode (i.e., only see the beautified photo). A regression analysis revealed the predicted 2 (evaluation mode: separate vs. joint) × continuous (self-construal) interaction (t(254) = 2.00, p < .05). Under joint evaluation mode, interdependents were more willing to use beauty app than independents (t(254) = 2.70, p < .01). However, there was no such effect when participants were under separate evaluation mode (t(254) = -.01, ns). The same effects were found on preference for sharing the beautified photo and self-overlap. Consistent with our theorizing, moderated mediation analysis (Model 7, Hayes 2013) revealed that self-overlap mediated the effect (CI: 0.1253, 0.6483). This study also ruled out social norms as an alternative explanation. Experiment 3 replicated the findings of Experiment 2 by priming self-construal.

Experiment 4 tested whether our effects would also hold when consumers took photos of themselves in real time in the lab. We measured self-construal and asked participants to try using the Beauty Plus app on a Samsung phone in the lab to take a beautified selfie. Afterwards, we either showed them only the beautified selfie or both the original and beautified selfies. A regression analysis on Beauty Plus use intention revealed the predicted 2 (evaluation mode: separate vs. joint) × continuous (self-construal) interaction (t(193) = 2.08, p < .05). When seeing both the original and beautified selfies, interdependents were marginally more willing to use Beauty Plus than independents (t(193) = 1.91, p = .058). In contrast, there was no such effect when participants only saw the beautified selfie (t(193) = -1.06, ns). Again, we found the same effect on self-overlap and demonstrated its mediating role.

Experiment 5 further tested the mediating role of self-overlap by manipulating it. After completing the self-construal measure, participants were randomly assigned to either the self-overlap attenuation condition in which they read a research article showing that engaging in beauty work can be viewed as disguising one’s true self or the condition in which they read a research article showing that engaging in beauty work is widely accepted in society. Afterwards, all the participants read the same beauty app ad as in Experiment 1 (joint evaluation). Results revealed a significant 2 (self-overlap attenuation vs. control) × continuous (self-construal) interaction (t(207) = -2.12, p < .05) on beauty app use intention. In the control condition, interdependents were more willing to use the beauty app than independents (t(207) = 3.05, p < .01). In contrast, there was no such effect when participants were in the self-overlap attenuation condition (t(207) = -1.14, ns).

In sum, this research not only provides insight into which consumers are more likely to use beauty apps and why, but at the theoretical level it shows for the first time that interdependents not only see greater overlap between themselves and significant others (Markus and Kitayama 1991), but also see greater overlap between their own different selves (true vs. ideal self).

Inspirational Aesthetics: How Beautiful Products Motivate Performance

EXTENDED ABSTRACT

In their influential paper, Hamermesh and Biddle (1994) identified a beauty premium in which beautiful people earned 4.8% more in the marketplace as compared to their less attractive counterparts. The premium is attributed to the “what is beautiful is good” effect: the phenomenon that physically attractive people are believed to have a wide array of positive personal traits, including intelligence, health, and competence (Dion, Berscheid, and Walster 1972). As with people, these aesthetic variations may or may not reflect real differences in a product’s ability to perform. In our research, we control for a product’s real ability to perform (i.e., its functionality) and focus on understanding how differences in product attractiveness influence users’ self-efficacy, motivation, and actual task performance.

In the first two studies, we find that when individuals partner with beautiful products to complete a task, they essentially “bask in the glory” of these objects, assimilating toward them and reaping positive benefits from the collaboration (e.g., Cialdini et al. 1976). This effect is due, at least in part, to individuals’ tendencies to look to these objects as partners and assimilate toward them as they might when collaborating with successful teammates (e.g., Greenberg et al. 2008). Individuals are more likely to look toward objects as social entities—whether consciously or unconsciously—when they are alone (Epley, Waytz, and Cacioppo 2007). Hence, in our third study we manipulate the presence of another collaborative and upward social comparison target during the task.

In study 1, participants were randomly assigned to either a more attractive 5 lb. weight, a less attractive 5 lb. weight, or both weights (choice condition). Participants were then asked to complete a set of basic weight exercises using the assigned or chosen weight. As with all of our studies’ stimuli, pretests showed that the attractive weight was judged to be more attractive, but equally functional. Self-efficacy was measured with three 7-point items (e.g., “I was self-assured of my ability to complete this exercise successfully”; α = .82; Bandura 2006).

As predicted, a one-way ANCOVA controlling for mood and gender revealed a positive effect of product attractiveness (F(1,124) = 3.32, p < .05). As predicted, participants in the more attractive and choice conditions reported higher self-efficacy than those in the less attractive condition (both p’s < .05). There was no significant difference between those in the choice and in the attractive conditions (p > .8), suggesting usage alone is sufficient for the effect to occur.

In our second study, participants were assigned to use either the more or less attractive weight and to complete the same task. Self-efficacy was measured as in study 1 and motivation was measured with four items (e.g., “These materials motivated me to exercise”; α = .72). The ANCOVA, controlling for gender and hedonic responses, revealed a positive effect of product attractiveness on both self-efficacy (F(1,106) = 4.43, p < .05) and motivation (F(1,106) = 3.59, p = .06). Mediation analyses indicated a significant indirect (i.e., mediation) effect of self-efficacy on the relationship between product attractiveness and motivation (bias-corrected 95% CI = [.0196, .3785]; Hayes 2012). The more attractive products increased self-efficacy, which translated into greater motivation. In the remaining studies, we focused on motivation and task performance as our primary dependent variables.

In our third study, we manipulated product attractiveness (more attractive vs. less attractive) and introduced a moderator: the availability of an upward comparison target. All participants completed this task in lab workstations using functionally equivalent and more (vs. less) attractive materials (e.g., cutting board, utensils, bowls) to cook a spring roll. Participants in the upward comparison target present condition were told to imagine that they were cooking in the presence of a member of a cookbook publishing company. Those in the upward comparison target absent condition were told to imagine themselves in a private space with no one else present. We predicted that when no upward comparison target is salient (as in studies 1 and 2), participants will report greater motivation (measured with the...
same four items as in study 2; α = .71). However, when a social comparison target is salient, the effect will be attenuated. As predicted, we found a significant interaction of the two factors on motivation (F(1,194) = 5.97, p < .05). When no human social comparison target was made salient, there was a significant positive effect of attractiveness on motivation (p < .01), but the effect was non-significant when the social comparison target was present.

In our final study, all participants were randomly assigned to a cooking workstation which included all the ingredients, materials and relevant tools needed to make a fruit kebob. The ingredients were identical across conditions and the materials were pretested to be either more or less attractive. After the study, photographs of the kebobs were randomized and distributed to ten judges (blind to condition) who evaluated the outcomes (i.e., how appealing, well-made, and delicious it looked; all α’s > .85). A one-way ANCOVA, controlling for gender and the hedonic responses, revealed a main effect of product attractiveness (F(1,119) = 6.37, p < .05). Kebobs produced using more attractive products were judged to be better than those produced using the less attractive products. While our earlier studies demonstrate the benefits of attractive products on consumers’ self-efficacy and task motivation, this final study shows that they not only feel more competent and motivated, but actually perform better when using more attractive, but functionally equivalent, materials.

Exploring Anthropomorphism Through the Lens of Agency and Communion
Chair: Linyun W. Yang, University of South Carolina, USA

SESSION OVERVIEW

The phenomenon of anthropomorphism is a rich and nuanced area of research that has captured the attention of many researchers in recent years (Aggarwal & McGill 2017). This session focuses on answering the question: How does attributing physical and mental human characteristics to nonhuman entities shape consumers’ understanding of and interactions with these entities? In the same way that they perceive other people, consumers are interested in assessing the intentions of an anthropomorphized entity and its ability to carry out those intentions, which correspond to communion and agency, respectively (Fiske et al. 2007). More specifically, communion relates to relationship building and social functioning (e.g., warmth, kindness) while agency relates to goal-achievement and task-functioning (e.g., competence, assertiveness; Abele & Wojciszke 2014). This session features four papers that study anthropomorphism from the perspective of agency and communion using different approaches.

First, Wang, Tourné-Tillery, and McGill demonstrate that anthropomorphizing a disease highlights the disease’s agency and reduces the psychological distance between the self and the disease. Consequently, consumers feel greater vulnerability and need to protect themselves from this ill-intentioned adversary. Next, Wang and Aggarwal highlight the importance of communion when they show that consumers rely on social norms when assessing anthropomorphized products, such that they choose to uphold sacred ‘moral’ values that dictate how living beings should be treated – even at a monetary cost to themselves.

The next two papers examine issues that affect both fundamental dimensions simultaneously. Olson and Mourey show that consumers expect anthropomorphized assistants (e.g., Alexa) to be high in both communion (like humans) and agency (like machines), making consumers less tolerant of poor performance from anthropomorphized assistants versus non-anthropomorphic or human assistants. Finally, Yang and Aggarwal demonstrate that anthropomorphism activates gender biases usually reserved for humans, such that products anthropomorphized are expected to be communal while product anthropomorphized as male are expected to be agentic.

Each paper in this session also incorporates in its own way this year’s conference theme of “Becoming Wise.” By integrating the theories of protection motivation (Wang et al.) and taboo trade-offs (Wan & Aggarwal), these papers expand wisdom by applying well-established psychological theories to understand important consumer contexts. Olson and Mourey demonstrate that new technology like digital assistants embody both human and machine-like qualities and are therefore perceived differently from more traditional sources of information. Finally, Yang and Aggarwal document our collective wisdom about anthropomorphism through the lens of gender to stimulate future extensions and theory development in this area.

Reflecting anthropomorphism’s pervasiveness in human judgment, various cultures, and all aspects of life (Aggarwal & McGill 2017), the papers in this session examine a broad range of contexts and demonstrate important implications for whether consumers believe nonhuman entities wish to inflict harm, deserve care and consideration, are responsible for their actions, and possess specific human traits. Therefore, this session will also appeal to researchers working in areas beyond anthropomorphism, including those interested in health behaviors, artificial intelligence, morality, and gender.

EXTENDED ABSTRACT

Communicators and consumers alike routinely anthropomorphize diseases and health concerns. Does thinking about a disease or health trouble in human terms—rather than in object terms— influence consumers’ judgments and behaviors with respect to that disease? This question is important because global and national public health organizations devote substantial resources to informing people about preventable risk factors—including tobacco use, unhealthy diets, and low physical activity—that lead to many deadly diseases. For example, in 2017, the Center for Disease Control and Prevention had a budget of about $12 billion devoted to critical science research as well as the dissemination of health information. Furthermore, the US government spent $13 million on anti-smoking ads in 2010 (Creamer 2012). Despite these efforts, getting the public to comply with health recommendations can be challenging.

The present research explores the effect of anthropomorphizing diseases on consumers’ compliance with health recommendation. Theories of anthropomorphism advance that one reason people anthropomorphize non-human entities is to gain a better understanding by conceiving of them in terms of the more familiar human schema (Epley et al. 2007; Epley, Akalis, et al. 2008; Epley, Waytz, et al. 2008). Thus, people treat and respond to anthropomorphized objects in ways that mirror their responses to comparable persons in the same context (Ahn, Kim, and Aggarwal 2014; Aggarwal and McGill 2007; Landwehr, McGill, and Herrmann 2011; Tam et al. 2013; Wan et al. 2017). We hypothesized that by making a negative object such as a disease more agentic and by reducing the psychological distance between the self and the disease, anthropomorphizing a disease will increase people’s sense of being at its mercy; that is, anthropomorphism will increase their perceptions that they are vulnerable to the disease. In turn, protection motivation increases as perceptions of vulnerability increase (Floyd and Prentice-Dunn 2000; Helmes 2002; Leventhal and Watt 1966; Milne et al. 2000; Rippetoe and Rogers 1987).

Study 1 tested the correlation between anthropomorphism and protection motivation. In the middle of flu season, we assessed undergraduate students’ (N = 200) general tendency to anthropomor-
phize, using the Individual Differences in Anthropomorphism Questionnaire (Waytz et al., 2010), and then we asked them to indicate whether they got a flu shot. We found a positive relationship between participants’ tendency to anthropomorphize and their likelihood to have taken steps to protect themselves from the flu ($\beta = .47; \chi^2(1) = 20.35, p < .001$).

Study 2 tested the mediating roles of psychological distance and perceived vulnerability. Female MBA students ($N = 159$) read a paragraph about breast cancer, in which the disease either “talked” about itself in the first person or was discussed in object terms (Puzakova et al., 2013; Touré-Tillery and McGill, 2015). Then they indicated their likelihood to take preventive steps against this disease, and the extent to which they felt close to and vulnerable to the disease. We found participants who thought of breast cancer in anthropomorphized (vs. object) terms felt closer to ($M_{\text{anthro}} = 3.35, SD = 1.35; M_{\text{object}} = 2.80, SD = 1.28, t(157) = 2.60, p = .010$) and more vulnerable to the disease ($M_{\text{anthro}} = 3.58, SD = 1.19; M_{\text{object}} = 3.15, SD = 1.05, t(157) = 2.45, p = .016$), and hence were more motivated to protect themselves from it (sequential mediation) ($M_{\text{anthro}} = 5.02, SD = 1.37; M_{\text{object}} = 4.55, SD = 1.33, t(157) = 2.18, p = .031$). Post study showed disease anthropomorphism did not influence measures of affect (positive affect: $t(140) = .53, p = .616$; negative affect: $M_{\text{anthro}} = 3.24, SD = 1.13; M_{\text{object}} = 3.50, SD = 1.10, t(140) = 1.40, p = .165$); negative affect: $M_{\text{anthro}} = 3.24, SD = 1.13; M_{\text{object}} = 3.43, SD = 1.32, t(140) = .53, p = .997$) and global evaluations of the disease ($M_{\text{anthro}} = 5.35, SD = 1.08; M_{\text{object}} = 3.35, SD = 1.16, t(140) = .03, p = .973$).

The next two studies tested the moderating role of high and low perceived vulnerability (respectively) on the effect of disease anthropomorphism on protection motivation. In study 3, we operationalized high vulnerability by giving participants (false) personalized information about their high risk of high blood pressure. Participants without blood pressure issues ($N = 305$) were recruited on Prolific Academic to read a paragraph about high blood pressure (HBP) describing the disease in human or object terms. Depending on the condition, participants received additional information about their own high risk of high blood pressure (high-vulnerability condition) or no such information (control condition). They then indicated their perceived vulnerability (respectively) on the effect of disease anthropomorphism ($M_{\text{anthro}} = 4.90, SD = 1.03; M_{\text{object}} = 4.97, SD = 1.17, t(301) = -3.6, p = .001$). Participants were less vulnerable to the disease ($M_{\text{anthro}} = 2.12, SD = 1.22; M_{\text{object}} = 2.08, SD = .98, p = .396$).

In study 4, we operationalized low vulnerability by giving participants (false) feedback about the strength of their immune system. Undergraduate students ($N = 300$) first completed a health and wellness survey and learned that they had either a strong immune system (low vulnerability) or an average immune system (control). They then read a brief message about Strep E (a fictitious disease), describing the disease in human or object terms, and then they answered questions assessing their protection motivation. We replicated the effect of disease anthropomorphism on protection motivation in the control condition ($M_{\text{anthro}} = 5.29, SD = 2.03; M_{\text{object}} = 4.77, SD = 1.26, t(301) = 2.46, p = .014$), but not in the low-vulnerability condition ($M_{\text{anthro}} = 4.90, SD = 1.03; M_{\text{object}} = 4.97, SD = 1.17, t(301) = -3.6, p = .001$).

Taken together, these studies show people are more motivated to protect themselves from an anthropomorphized (vs. object) disease, because they feel psychologically closer and more vulnerable to the disease. Our research contributes to theory and practice in the areas of protection motivation and health communication by identifying a novel factor that increases protection motivation by increasing perceptions of vulnerability: disease anthropomorphism.

**Products are People Too! Making Taboo Trade-Offs with Anthropomorphized Products**

**EXTENDED ABSTRACT**

Anthropomorphism is the tendency to attribute human traits to nonhuman entities. For example, people often name their cars and talk to their computers or phones as if these machines are living beings. Past research has shown that consumers (mis)apply human norms when interacting with anthropomorphized products. For example, since it is inappropriate to assess people on their functional value, consumers are less willing to replace their old cars if these cars are anthropomorphized (Chandler and Schwarz, 2010). People also show greater likelihood to help an anthropomorphized social cause because it is inappropriate to not help a human being who is in need (Ahn et al., 2014).

Economic exchange is an integral part of marketplace settings—product attributes are routinely traded off for money. Consumers often look for the best deals and try to get more “bang for their buck.” However, we argue that consumers may not have this “commercial” mindset when it comes to anthropomorphized products. Past research finds that the exchange of human values for money is morally repugnant (e.g., selling organs for money; Tetlock, 2003). Some values are seen as sacred (love, loyalty) whereas others are more secular (money)—people find trade-offs between sacred and secular values to be aversive. In fact, even buying or selling products associated with people who have special relational significance can be discomfiting (McGraw and Tetlock, 2005).

While products are typically bought and sold with money, we posit that endowing a product with humanness may replace marketplace exchange norms with social relational norms. As such, consumers may forgo monetary gains in order to avoid making aversive trade-offs. Across four studies, we show that consumers are willing to sell at lower prices and buy at higher prices because thinking about monetary value feels “wrong” when it comes to buying and selling anthropomorphized products.

**Study 1** takes the context of saving money by replacing an old product rather than repairing it. Participants imagined owning a wrist watch; half of the participants wrote about the watch coming to life (anthropomorphized) and the other half wrote about the watch as a mechanical object (objectified). They were then informed that the watch, while under warranty, developed a mechanical issue, and they had two options: 1) replace the broken watch with a similar new one at no cost, or 2) pay a shipping fee and send the watch in for repairs at no additional cost. Participants preferred to repair the watch when it was anthropomorphized than if it was objectified ($M_{\text{anthro}} = 4.14, M_{\text{object}} = 3.66; F(1, 176) = 4.10, p = .04$).

**Study 2** takes the context of getting a higher price for selling a product that would be broken down and used for parts. Participants imagined owning an old car, which they wanted to sell. The car was either described in anthropomorphized terms or not. Participants received two offers: one was from an end user (a student) who wanted to use the car as is; the other from the owner of a salvage yard who was looking to buy a car to use for parts. The yard owner offered more money than the student. Participants then indicated their preference between the two potential buyers. Participants were less willing to sell the car to the salvage yard if it was anthropomorphized than if it was objectified ($M_{\text{anthro}} = 1.57, M_{\text{object}} = 2.15; F(1, 139) = 4.26, p = .04$).

**Study 3** takes the context of buying products to examine if haggling on the price of a humanized product would feel inappropriate. Participants were shown a Facebook Marketplace post where a used sofa was listed for sale: the sofa was either anthropomorphized or...
The cost of genuine interpersonal interaction (Mourey, Olson, and Yoon 2017).

Although Alexa is not equivalent to a human being, consumers might apply the “universal dimensions” of social perception to non-human sources (Fiske et al. 1999, 2002). Namely, consumers may perceive anthropomorphic products as varying in warmth (friendliness, good intentions) and competence (efficiency, ability), comparable to the way they perceive fellow humans. If so, these perceptions might have implications for performance expectations and subsequent support when these sources provide information.

We examine these propositions by comparing three information sources: anthropomorphic forecasters, non-anthropomorphic forecasters, and human forecasters. When these sources provide accurate forecasts, we anticipate similar levels of consumer support; however, when these sources provide inaccurate forecasts, we anticipate differential consumer support. We propose that anthropomorphic forecasters will be seen as both warm (Alexa—human) and competent (machine—precision). As a result, they elicit the strongest expectations from consumers and suffer the most from poor performance. Conversely, human forecasters may be seen as more warm than competent (i.e., lower performance expectations), meaning they should be more easily forgiven following an inaccurate forecast. Non-anthropomorphic forecasters, seen as more competent than warm, may elicit greater expectations than humans (i.e., they benefit from a machine’s precision) but not as high as anthropomorphic forecasters (i.e., they still lack warmth). Although expectations may be greatest for anthropomorphic devices, consumers do not uniquely reward them following accurate forecasts; instead, poor performance is punished, relative to human and non-anthropomorphic sources. We provide support for these predictions in a series of five studies.

We began with a pilot study in the domain of weather forecasts. Participants (N=423) were randomly assigned to evaluate one of three information sources: Amazon’s Alexa (anthropomorphic), a weather app (non-anthropomorphic), or a meteorologist (human). Dependent measures included perceived accuracy, expected accuracy, and the permissible margin of error. Consistent with predictions, participants had the greatest expectations for Alexa relative to the weather app or human forecasters (p<.05). Participants were also less tolerant of mistakes from Alexa relative to the other two sources (p<.06).

Study 1 featured the same three information sources, but this time we manipulated accuracy directly. Specifically, participants (N=300) read that the source was either “performing as expected at 85%” or “performing below expectations at 40%.” Results revealed similar levels of consumer support (i.e., trust, willingness to use in the future) across the three sources when it was performing as expected (p>.55). However, when the source performed below expectations, participants were less supportive of Alexa relative to the app and the meteorologist (p<.01).

Study 2 provided a conceptual replication of Study 1 using a traffic context. The design was identical, but this time we added exploratory warmth and competency measures. Participants (N=300) expressed similar levels of support when the source performed as expected (p>.47), but poor performance significantly impaired Alexa relative to the traffic app and human traffic forecaster (p<.01). Subsequent analyses revealed that (regardless of performance) humans were perceived as relatively more warm than competent (p<.001),
the app was relatively more competent than warm \((p<.001)\), and Alexa was equally warm and competent \((p=.13)\). Warmth showed the greatest divergence across sources and so we focused on warmth in Studies 3 and 4.

Study 3 examined whether Alexa’s punishment following poor performance could be mitigated via warmth. Participants \((N=414)\) were randomly assigned to evaluate either Alexa or a human meteorologist who was performing below expectations. We also manipulated the presence or absence of warmth information (i.e., “Even though X gets the forecast wrong sometimes, please remember that there are people behind X’s forecasts…” these employees are dedicated, have positive intentions, and take a genuine interest in helping others”). While warmth did not influence support for meteorologists \((p=.67)\), reminding participants that Alexa is powered by humans resulted in greater support \((p=.032)\).

Study 4 \((N=242)\) featured a similar design as Study 3 with two exceptions: 1) Alexa herself (vs. behind-the-scenes employees) was imbued with warmth or not and 2) we measured perceived warmth. Moderated mediation analysis revealed that, in the absence of a warmth boost, participants indicated lower intentions to use Alexa relative to a human source \((p<.001)\); this was mediated by the perception that Alexa possessed less warmth \((p=.006; 95\% \text{ CI}: -.63, -.07)\). However, with a warmth boost, Alexa was essentially identical to a human source in warmth \((p=.87)\), which meant participants were equally willing to use Alexa versus a meteorologist even after evidence of poor performance \((p=.26; 95\% \text{ CI}: -.17, .22)\).

In sum, five studies provide evidence that consumers have different expectations for information sources as a function of anthropomorphic qualities. As a result, consumers are more or less forgiving of these sources following poor performance. Anthropomorphic devices suffer the burden of needing to be equal parts warm and competent, whereas humans can be relatively warm and mobile apps can be relatively competent. Anthropomorphic devices do not get the “warmth” reprieve that humans do following poor performance unless provided with an extra warmth boost. Thus, greater expectations result in less support following evidence of poor performance.

Is Male the Default Gender? The Distinctive Effects of Anthropomorphizing Products as Male versus Female

EXTENDED ABSTRACT

In the last decade, we have seen an explosion of research exploring the antecedents and consequences of anthropomorphism. Despite being a fundamental trait of humanness, the gender of an anthropomorphized entity has remained largely unexamined. Are anthropomorphized entities perceived as possessing gender and, if so, are they perceived as female or male? How might consumers perceive and interact differently with female versus male entities? Can we expect gender stereotypes prevalent in the social world to be operating in the brand world too?

To answer these questions, we draw on the phenomenon of androcentrism whereby men are viewed as the gender-neutral standard while women are perceived as gender-specific (Bailey et al. 2018). For humans, male is the default and male terms are used to represent both genders (e.g., using “guys” when referring to a mixed-gender group), but female terms refer specifically to women. Additionally, research has documented strong gender stereotypes: women are associated with communal traits like kindness, warmth, and sympathy while men are associated with agentic traits like assertiveness, competence, and independence (Eagly & Steffen 1984).

In our first two studies, we demonstrate that when the gender of the anthropomorphized entity is unspecified, androcentrism will emerge. In study 1, the phenomenon of androcentrism manifests across a broad range of anthropomorphized products. In study 2, a brand anthropomorphized as female versus male is be perceived differently in terms of communion and agency in keeping with the gender stereotypes prevalent in our social world. Importantly, when the anthropomorphized brand’s gender is unspecified, the product is perceived as masculine and similar to when the brand is anthropomorphized as male.

Study 1: 218 Mturk participants were assigned randomly to 5 out of 20 possible nonhuman entities and asked to imagine each entity had to come to life as a person and to describe a day in the entity’s life. These entities included abstract concepts like time and nature, concrete objects like a sofa, and television, and edible objects like a hamburger and sushi roll. Results from two independent coders indicated that on average, the majority of participants \((65\%)\) spontaneously attributed gender to anthropomorphized entities, with more participants attributing male \((46\%)\) than female gender \((19\%\): \(\chi^2=12.00, p<.05\)). Moreover, coding \((1=very masculine, 7=very feminine)\) indicated that anthropomorphized entities were on average described as more masculine \((M=3.69, H_{\alpha}=4, p<.0001)\). Finally, when directly asked about each entity’s gender, results across all entities showed that 66.3% of the participants selected male while 33.7% selected female \((\chi^2=5.45, p<.05)\).

Study 2: 313 Mturk participants evaluated a coffee company anthropomorphized as male (Mr. Bean Coffee Co.), female (Ms. Bean Coffee Co.), or with no gender specification (Bean Coffee Co.). Participants were asked to rate the company on five personality traits with lower values indicating femininity and higher values indicating masculinity (e.g., 1=cooperative, 7=competitive, \(a=.97\)). Ms. Bean was rated the least masculine \((M_{\text{Masc}}=3.78, M_{\text{Fem}}=4.25, M_{\text{Neut}}=4.21, p<.01)\) while Mr. Bean and Bean were not rated differently. Gender-based expectations also influenced product attribute ratings (e.g., 1=sweet, 7=bitter, \(a=.71\)). Ms. Bean was rated as tasting more in keeping with feminine stereotype \((M_{\text{Masc}}=3.87, M_{\text{Fem}}=4.22, M_{\text{Neut}}=4.32, p<.01)\) than Mr. Bean and Bean, the latter two were not rated differently. Consistent with these ratings, when asked to determine the brand’s gender in the unspecified condition, participants overwhelmingly perceived Bean to be male \((89\%)\). Overall, these results show a strong androcentrism effect for anthropomorphized entities.

Study 3: Given that women are perceived as gender-specific while men are viewed as the gender-neutral standard, stereotypical gender association may be stronger for female entities compared to those for male entities. While female entities are expected to remain within the narrow confines of femininity, male entities are expected to vary to a greater extent. We predict that for brands anthropomorphized as female, consumers will perceive a greater match for gender-consistent product features; for brands anthropomorphized as male, this will not be the case.

596 Mturk participants evaluated a coffee company anthropomorphized as male (Mr. Bean Coffee Co.), female (Ms. Bean Coffee Co.), or not anthropomorphized (Bean Coffee Co.). The coffee was described as having either masculine (dark, bold, bitter) or feminine (light, delicate, sweet) flavors. For Ms. Bean, participants perceived a greater match (e.g., Product flavors seemed appropriate, \(a=.97\)) when the coffee had feminine versus masculine flavors \((M_{\text{Fem}}=5.95, M_{\text{Masc}}=5.40, p<.05)\). However, flavor stereotypicality had no effect on matching perceptions for Mr. Bean \((M_{\text{Fem}}=5.68, M_{\text{Masc}}=5.59, NS)\) or Bean Coffee Co. \((M_{\text{Fem}}=5.64, M_{\text{Masc}}=5.58, NS)\).

Study 4: Finally, we test for the moderating role of consumers’ interpersonal goals on androcentrism for anthropomorphized products. To the extent that consumers see products as extensions...
of themselves and forms of self-expression (Belk 1988; Bodner & Prelec, 2003), consumers should be motivated to view an anthropomorphized product in a way that helps convey desirable traits to others. We predict that when consumers have a dominance goal, androcentrism will persist because the desired traits are stereotypically masculine; however, when consumers have an affiliation goal, androcentrism will be attenuated because the desired traits are stereotypically feminine.

358 Mturk participants imagined that they were considering a rental car for either an important business trip (dominance goal) or to meet up with a new friend (affiliation goal). The car was either anthropomorphized (e.g., speaking in first person) or not anthropomorphized (e.g., described in 3rd person). Perceived gender was measured in two ways. First, participants rated the car on the same traits used in Study 2. Results indicated that activating a dominance versus affiliation goal garnered more masculine personality ratings ($M_{dom}=3.79$, $M_{aff}=3.37$, $p<.05$), but only when the car was anthropomorphized. Next, participants were asked to give the rental car a name. Coding of these names (i.e., male, female, neutral) indicated that activating a dominance goal garnered more male (59%) than female names (28%, $\chi^2=6.31$, $p<.05$), exhibiting androcentrism. Activating an affiliation goal attenuated this androcentrism effect (male=49%, female=36%, $\chi^2=.06$, NS).

In sum, this research contributes by presenting gender as an important lens for a nuanced understanding of anthropomorphism and also by being the first to suggest an asymmetry in how gender is attributed to anthropomorphized entities.

SESSION OVERVIEW
Consumers are susceptible to context. A rich literature in marketing and psychology has explored context effects as theoretically important deviations from normative choice principles and as practical interventions to shift consumer choices. For example, adding a new option to the choice set can shift decisions by increasing the share of the middle option (Simonson, 1989; Simonson and Tversky, 1992), increasing the share of the asymmetrically dominant alternative (Huber, Payne, and Puto, 1982; Huber and Puto, 1983), prompting choice deferral by heightening decision conflict (Dhar, 1997; Tversky and Shafir 1992; Shafir, Simonson and Tversky 1993), and triggering preference reversals by enhancing attribute evaluability (Hsee 1996, Hsee et al. 1999; Hsee and Zhang 2010).

While context effects have been well-documented, the boundary conditions under which they occur have been less studied. In fact, the robustness of some context effects across different trade-offs and representations has recently been debated (Evangelidis et al 2018, Frederick, Lee and Baskin, 2014; Huber, Payne and Puto, 2014; Simonson, 2014; Yang, & Lynn, 2014). The research in this session seeks to develop a richer understanding of the conditions under which context influences the evaluation of options. We investigate how choice sets and the characteristics of attributes interact to influence consumer decision-making process, highlighting the crucial role of how people make comparisons.

The first two papers investigate the robustness of context effects to how the options are presented. Contrary to prior research (Frederick, Lee and Baskin, 2014), Wang and Urminsky find robust evidence of attraction effects when both choice options are presented pictorially, which is enhanced when prompting people to compare the attributes. Employing a joint experimental and computational modeling approach, Trueblood, Evans, and Holmes propose a theory that decisions arise from series of simple comparisons among options, giving rise to context effects. The theory predicts context effects will arise when options are presented sequentially in some orders but not others, consistent with their experimental results.

The last two papers investigate how the number of options (i.e. joint evaluation vs single evaluation) moderates consumer decisions. Evangelidis, Levav, and Simonson reconcile conflict-based and evaluability-based explanations of choice deferral. They show that when the alternatives’ attributes are not highly evaluable or attractive in isolation, making comparison difficult, people defer choices less in joint evaluation than in single evaluation. Li and Hsee examine how context shapes the relative influence of evaluability and justifiability of options. They find that low-evaluability attributes are more influential in joint evaluation, which fosters comparisons, and low-justifiability attributes are more influential in single evaluation, which impedes comparison.

This session sheds light on the robustness of and pre-conditions for context effects. Overall, the research highlights the key role of comparisons for context effects, demonstrating that factors which shift the ease and likelihood of comparisons change the prevalence of context effects. This research contributes to reconciling prior debates about the robustness of and reasons for context effects (focusing on the attraction effect, choice deferral and joint-separate evaluation), and has broad implications for research on choice architecture and for marketing practices.

“Seeing” the Attraction: The Attraction Effect in Choices Between Visual Stimuli

EXTENDED ABSTRACT

The attraction effect refers to situations in which introducing an inferior option (i.e. a decoy) to the choice set of two alternative options increases the choice share of the option that resembles and dominates the decoy (i.e. the target) relative to that of the dissimilar option (i.e. the competitor) (Huber, Payne, and Puto, 1982; Huber and Puto, 1983). Past research has demonstrated the robustness of the attraction effect in various context such as choosing products and evaluating political or job candidates. However, whether the attraction effect occurs when the options or option attributes are presented perceptually (rather than quantitatively) is still highly controversial (e.g. Frederick, Lee, and Baskin, 2014; Kivetz, Netzer, and Srinivasan, 2004; Spektor, Kellen, and Hotaling, 2018; Trueblood, Brown, Heathcote, and Busemeyer, 2013; Trueblood and Pettibone, 2017). Evidence from four pre-registered experiments showed that the visual attraction effect does exist, it requires correct perceptions of the relationships between the attribute values, and is amplified by prompting participants to make trade-offs between attributes.

Study 1 (N=716) was a replication and extensions of Frederick, Lee, and Baskin’s (2014) Study 3c. We also explored whether the attraction effect occurs specifically when participants successfully detected the relative attractiveness of each option on each attribute (i.e. perceived the decoy as asymmetrically dominated by the target). We used a 2 (task sequence: ratings precede choices vs choices precede ratings) × 2 (choice sets: no decoy vs with decoy) between-subjects design. Participants were told that they were going to buy a second television and there were a few options available. These options had
the same screen size but varied in price (presented numerically) and image quality (presented pictorially). Participants rated the attractiveness of the price and of the image quality of each television, either before or after making their choice among the televisions.

We successfully replicated Frederick, Lee, and Baskin (2014). The provision of the decoy significantly increased the choice share of the target over the competitor when ratings preceded choices (28% vs. 43%, chi²=7.36, p<.007) but not when choices preceded ratings (34% vs. 36.5%, chi²=.19, p=.662). Thus, ratings-first enhanced the decoy effect (β=.55, S.E.=.34, z=1.63, p=.102). However, when presented with visual stimuli, people may not perceive the decoy as dominated by the target. Using only the subset of the data where all participants successfully detected the relative attractiveness of each option on each attribute, we found more nuanced results. When participants rated both attributes before making their choices, the inclusion of decoy increased the share of the target (27% vs. 48%, chi²=10.21, p=.001). When ratings followed choices, a directional attraction effect also emerged (32% vs. 41%, chi²=2.08, p=.150).

Study 1, like the prior research it was based on, confounds visual presentation with differential ease of processing, since image is presented visually but price is presented as a number. Study 2a (N=835) tested the attraction effect when both product attributes were presented pictorially, varying whether participants rated the attributes before or after making the choice, as in Study 1. The choice sets consisted of equally priced televisions with different image quality and screen size, each presented visually as a separate attribute. A logistic regression with the choice of the target as dependent variable revealed the attraction effect whether ratings preceded the choices (26% vs. 57%, chi²=38.59, p<.001) or choices preceded ratings (40% vs. 58%, chi²=12.19, p<.001). The attraction effect was larger when participants rated the items before choice (βinteraction=.59, S.E.=.29, z=2.41, p=.016). Additionally, the writing task reduced the share the decoy from 12% to 3% (chi²=13.23, p<.001). However, when presented with visual stimuli, people may not perceive the target as dominating the decoy, bolstering the attraction effect.

Study 1 showed a stronger effect (26% vs. 54%, chi²=31.34, p<.001) than those in the control condition (46% vs. 59%, chi²=6.71, p=0.101; βinteraction=.71, S.E.=.29, z=2.41, p=.016). Additionally, the writing task reduced the share the decoy from 12% to 3% (chi²=13.23, p<.001). The results remained significant in the subset of data where participants successfully detected the relative attractiveness of the options. Thus, the writing task yielded similar attraction effects, and identifies the detectability of the decoy and the likelihood of engaging in attribute comparisons as moderators of the strength of the attraction effect.

### Context Effects Explained through the Accumulation of Simple Comparisons

**EXTENDED ABSTRACT**

One of the most interesting findings in the multi-alternative, multi-attribute choice literature is the effect of introducing a new alternative on preferences for existing alternatives. Decades of research have shown that preferences are sensitive to the context created by the choice set (e.g., the attraction effect). Although context effects have been documented in numerous studies, the specific circumstances necessary for them to occur is a puzzle. Sometimes, the effects disappear and even reverse, suggesting that they are fragile (Frederick, Lee, & Baskin, 2014; Trueblood, Brown, & Heathcote, 2015). The present work describes a theory of the cognitive processes involved in multi-alternative, multi-attribute and how these processes can lead to context effects in some situations and not others. The theory is formalized using mathematical and computational modeling, allowing for precise predictions and rigorous theory testing.

Our hypothesis is that decisions arise from a sequence of very simple comparisons among options. To illustrate, consider the problem of selecting a new apartment out of three possible candidates (labeled A, B, and C) where the attributes of interest are ‘general condition’ and ‘distance to work’. In this scenario, the simplest possible comparisons that a person can perform are between two alternatives on a single attribute. In the proposed theory, we assume that people build up preference for different options through a sequence of these very simple pairwise comparisons. For example, in the apartment choice task, a participant might first compare apartments A and C along the ‘general condition’ attribute. Following this comparison, the participant might compare apartments B and C along the ‘distance to work’ attribute, and then they might compare apartments A and B along the ‘general condition’ attribute. This process continues until the participant has enough information to make a decision. We assume that the amount of information needed for the decision is governed by an internal threshold. As a person goes through the comparison process, he/she is updating the preference states for the different options until the preference state for one of the options surpasses the internal threshold, triggering a decision. In addition, we assume that the amount of time spent on a comparison is related to the similarity of the attributes being compared. We hypothesize that people spend more time comparing attributes that are more difficult to discriminate (i.e., more similar).

The above theory can be mathematically formulated as a random walk model, falling within the general class of sequential sampling models that are widely used in cognitive psychology and neuroscience (Ratcliff, 1978; Gold & Shadlen, 2007). Through model simulations, we show that the proposed theory explains the main three context effects – attraction (Huber, Payne, & Puto, 1982), compromise (Simonson, 1989), and similarity (Tversky, 1977). We also show that the model explains why the attraction and compromise effects vanish for advantageous as compared to disadvantaged options (Evangelidis,
Levav, & Simonson, 2018). Going beyond simulations, we discuss how the theory can be embedded within a choice/response time model (Trueblood, Brown, & Heathcote, 2014). Using this instantiation of the theory, we describe a large scale test (Evans, Holmes, & Trueblood, 2019) of the theory using data from 12 different experiments appearing in 6 different published studies (Trueblood, 2012; Trueblood, Brown, Heathcote, & Busemeyer, 2013; Trueblood, Brown, & Heathcote, 2014; Trueblood, Brown, & Heathcote, 2015; Farmer, Warren, El-Deredy, & Howes, 2017; Parrish, Evans, & Beran, 2015) examining the attraction, compromise, and similarity effects in risky decision-making, inference, and perception with both humans and non-human primates (total of 614 human and 7 non-human primate participants). The proposed theory is compared to three other theories of multi-alternative, multi-attribute choice (Roe, Busemeyer, & Townsend, 2001; Usher, & McClelland, 2004; Bhatia, 2013) and shown to be superior to all three across the 12 data sets.

A key idea in the proposed theory is that simple comparisons drive the evaluation of alternatives. In a new laboratory experiment (N=50), we increase the difficulty in comparing different options and examine the resulting influence on preferences. To accomplish this, we present options one at a time, so that individuals never see alternatives simultaneously. Specifically, we develop a sequential version of a well-established perceptual attraction effect paradigm where participants are asked to judge the area of rectangles that differ on the attributes of height and width (Trueblood, Brown, Heathcote, & Busemeyer, 2013; Trueblood, Brown, & Heathcote, 2015; Farmer, Warren, El-Deredy, & Howes, 2017; Parrish, Evans, & Beran, 2015; Turner, Schley, Muller, & Tsetsos, 2018). Empirical results show a complex pattern of attraction and repulsion effects (i.e., reversal of the attraction effect) in different sequences, with no obvious heuristic pattern of responding (e.g. choosing the last alternative). Critically, these effects arise only from the sequencing of stimuli and not the stimuli themselves; the same stimuli presented in different orders yield different effects. We explain the results using our proposed model augmented with the assumption that memory impacts the comparison process. Our hypothesis is that forgetting leads to different decisions in different sequences due to the difficulty of comparing items retrieved from memory with items currently visible. We demonstrate that our theory predicts well the complex pattern of attraction and repulsion effects seen in the data.

In sum, the proposed theory sheds new light on the ongoing debate about the robustness of context effects (Frederick, Lee, & Baskin, 2014; Huber, Payne, & Puto, 2014; Simonson, 2014; Yang, & Lynn, 2014). Importantly, we show that the apparent fragile nature of these effects can be explained by understanding the cognitive mechanisms underlying multi-alternative, multi-attribute decision-making. Through a joint experimental and computational modeling approach, we show behavior is well explained by a dynamic and malleable comparison process through which preferences are constructed. Importantly, our results suggest that determining the "boundary conditions" of the context effects (Huber, Payne, & Puto, 2014) will be best accomplished by understanding the "boundary conditions" of the comparison process and its interaction with other cognitive processes. Given the prevalence of sequential consumer search (Diehl and Zauberman 2005), our results also identify a new and practically important moderator of context effects.

**Revisiting the Dynamics of Deferred Decisions: An Evaluability-Based View of Choice Deferral**

**EXTENDED ABSTRACT**

In online settings consumers are presented with options either jointly or in isolation. For instance, a consumer browsing portable hard drives might be presented with information about a 1TB hard drive, in addition to information about a higher-priced 2TB hard drive. On a different site the consumer might be presented with information about the 1TB drive, but with no information about similar items. In both scenarios the consumer can select the 1TB drive or defer choice. In which of the two scenarios will the consumer be more likely to defer choice?

Studies of choice deferral make a straightforward prediction: choice sets comprising two (or more) options that force people to make trade-offs are more likely to lead to deferral (Dhar 1997; Tversky and Shafir 1992; Shafir, Simonson and Tversky 1993). Shafir, Simonson, and Tversky (p. 21, 1993; see also Tversky and Shafir 1992) argue that “there are situations in which people prefer each of the available alternatives over the status quo but do not have a compelling reason for choosing among the alternatives and, as a result, defer the decision, perhaps indefinitely.” This literature views choice deferral as a function of decision conflict—consumers are more likely to defer choice when they feel conflicted about what to choose. Choice sets that include a single option—as in the case of the second consumer in our opening example—do not create such a dilemma and the conflict that it evokes. Therefore, based on the canonical view of choice deferral, we would expect that the first consumer (i.e., the one faced with two options) would be more likely to defer choice compared to the second consumer (i.e., the one faced with a single option) because the former should feel more conflicted.

The conflict-based view traces deferral to preference uncertainty—a consumer is unsure which option to choose, so she chooses neither. However, consumers can also have uncertainty about the value of the option or options in the choice set—a consumer is unsure about whether or not a specific attribute level is valuable. Indeed, past research on evaluability suggests that people often have difficulty assessing the value of an attribute without a comparative context or reference (Hsee 1996, Hsee et al. 1999; Hsee and Zhang 2010). By this view, presenting consumers with options jointly facilitates an assessment of a target option’s value. The implication of this leads to a conclusion that appears at odds with the above-cited classic research on deferral. Namely, if joint presentation of alternatives makes them easier to evaluate, then deferral should decrease relative to presentation of a single alternative because joint presentation allows for easier resolution of uncertainty. With respect to our opening example, we expect that the first consumer (i.e., the one faced with two options) would be less likely to defer choice compared to the second consumer (i.e., the one faced with a single option) because evaluability is relatively higher in the former case.

In this paper we reconcile these two contradictory predictions about choice deferral in one framework that accounts for both conflict-based and evaluability-based explanations. We propose that deferral depends on the interaction between evaluability and option attractiveness. When the value of an alternative’s attribute cannot be easily evaluated or is not highly attractive in isolation, we predict that consumers will be more likely to defer choice when presented with a single option as opposed to when presented with two options. In other words, when consumers have uncertainty about the subjective value of the alternatives’ attributes so that they have difficulty assessing their utility from the options, they will defer choice. In contrast, the conflict-based prediction of choice deferral—that defer-
We have completed several experiments to test the propositions, and we briefly describe three experiments here. Experiment 1 tested Propositions 1 and 2, and included two type-of-attribute conditions: low-evaluability/high-justifiability and high-evaluability/low-justifiability. In both conditions, we asked jury-eligible US participants to assume the role of juror members, and determine the prison term for a US fighter pilot who mistakenly killed civilians in an overseas operation. Each participant read either two scenarios (JE) or one of the two scenarios (SE). In the low-evaluability/high-justifiability condition, the only attribute that differentiated the two scenarios was the number of civilians killed, either 10 or 20. In the high-evaluability/low-justifiability condition, the only attribute that differentiated the two scenarios was the ethnicity of the civilians killed, either Belgians or Somalians. Supporting Proposition 1, number of victims had a greater effect on the imposed prison term in JE than in SE ($\beta = -.26, p = .02$, by using a contrast code regression analysis). In contrast, supporting Proposition 2, the ethnicity of the victims had a greater influence in SE than in SE ($\beta = .43, p < .001$). Specifically, in JE, respondents imposed similar punishments on the fighter pilot whether he killed Belgians or Somalians, but in SE, respondents imposed significantly harsher punishment if he killed Belgians rather than Somalians.

In Experiment 2, we orthogonally manipulated the justifiability and the evaluability of an attribute, and tested all of the four propositions. We asked participants to rate the qualifications of two job candidates who differed on only one attribute—test score. We manipulated the evaluability of the score by using either numbers or words, and the justifiability of the score by telling participants whether they should base their ratings on the score or they should not do so. In JE, the two candidates were presented side by side, and in SE, the two candidates were separated by some fillers. The results supported our theory. In the low-evaluability/high justifiability condition, the score was more influential on participants’ ratings in JE than in SE, $F(1,130)=24.81, p < .001$, while in the high-evaluability/low-justifiability condition, the score is more influential in SE than JE, $F(1, 133)=6.11, p = .015$. In the low-evaluability/high-justifiability condition, the score was similarly influential, $p=.454$, and in the low-evaluability/low-justifiability condition, the score was similarly uninfluential, $p=.405$.

Experiment 3 was a field experiment. It focused on a high-evaluability/low-justifiability attribute (the ethnicity of a service seeker) and tested Proposition 2. We posted two tutor-seeking ads either jointly or separately on a service exchange website, and we described one of the tutor seekers as from Europe and the other as from Africa. We asked interested tutors to indicate their minimal-acceptable rates. We found that in JE, interested tutors charged the same amount for the two tutor seekers, $p = .216$, but in SE, interested tutors charged significantly higher prices for the African than for the European, suggesting that the ethnicity of the service-seeker had a greater influence in SE than in JE, $t(93)=2.20, p = .031$.

To the best of our knowledge, this is the first research to integrate both justifiability and evaluability in one theoretical framework. By doing so, it is able to explain many seemingly contradictory findings in the literature, and reconcile alternative accounts of JE-SE preference reversals. Because discriminatory factors are typically high-evaluability/low-justifiability attributes, this research also sheds light on how discriminatory factors influence decisions and how to mitigate such influences.

SESSION OVERVIEW

Much of consumer behavior involves thinking about the future. This is particularly true in recent years, as online platforms allow consumers to purchase and plan exponentially more services or activities in advance. As such, modern consumer decision-making relies on the ability to correctly anticipate numerous aspects of a future experience, such as how long it will last, the enjoyment or utility it will provide, and the degree to which the consumer can secure a good outcome. Together, the papers in this session explore beliefs about the future across all of these dimensions. We present novel biases, challenge existing ones, and examine consequences of those beliefs for consumer decision-making.

The first two papers investigate beliefs about the controllability of future outcomes. Williams and LeBoeuf show that people believe that the same outcomes will be more controllable in the future than they were in the past. This was true for both positive and negative outcomes. The authors propose that people may substitute their current perceptions of control over the past and the future when remembering the past and forecasting the future. This “illusion of future controllability” is complemented by work by Klusowski, Small and Simmons, who investigate whether the perception of control—absent actual control—makes future outcomes feel more likely. They find that illusionary control does not affect perceived likelihood of winning a lottery, contrary to extant literature on the topic. Rather, only choices that increase actual control increase optimism about future outcomes.

In the third paper, Tonietto demonstrates that consumers believe future experiences that are scheduled (vs. impromptu) will be of higher quality, and that they will be more satisfied with the outcome. These expectations seem to match reality. The author finds that the mere act of scheduling increases satisfaction with an experience. Moreover, when an experience went badly, consumers who scheduled still reported greater satisfaction than consumers who did not, because both groups adjusted from their expectations to a similar degree. Thus, scheduling may provide a buffer against dissatisfaction when an experience goes wrong.

Finally, Donnelly and Evers show that people perceive time periods as longer when they span more hour boundaries. For example, 1:30 – 3:00 (a boundary-expanded period) feels longer than 2:00 – 3:30 (which is boundary-compressed). The authors demonstrate that this perception may affect consumer decision-making. For example, consumers seemed to prefer boundary-compressed periods—which “feel shorter”—when scheduling unpleasant activities. Moreover, consumers required a higher amount of money to endure a long waiting period that was boundary-expanded compared to compressed. They were also willing to pay more to avoid boundary-expanded waiting periods than boundary-compressed.

Taken together, this session offers new insight into how people think about the future and demonstrates how those perceptions shape the consumer experience. Attendees will learn how people think about the controllability of future outcomes (Williams and LeBoeuf), how controllability shapes beliefs about future outcomes (Klusowski, Small and Simmons), and how consumers estimate and anticipate the duration (Donnelly and Evers) and quality (Tonietto) of future experiences.

Consumers Believe They Will Have More Control Over the Future than They Did Over the Past

EXTENDED ABSTRACT

Insanity, as the saying goes, is “doing the same thing over and over again but expecting different results.” People trying to diet, quit smoking, or be financially responsible may make a dozen attempts before they see meaningful results, if they see results at all (Polivy and Herman 2002). We argue that one important reason for this “failure to learn from failures” is that people expect to have greater control over future events than they would have had over identical past events. This is consistent with other work showing that the future (relative to the past) seems more premeditated (Burns et al. 2012), involves more willpower (Helzer and Gilovich 2012), and seems more rational (O’Brien 2015). Our work expands on this research, showing that for a variety of experiences, including negative and chance events, people believe they will have more control over the future than the past, and that this difference stems from an overgeneralized belief that the future is open and the past is fixed.

In study 1, participants rated whether they had more control over ten items, such as their diet and finances, last month, or whether they will have more control next month. Participants also rated whether they believed they would generally have more control over their lives last month or next month. For all ten items, participants anticipated having greater control next month than they had last month (significantly so in all but two cases). The general assessment also reflected a reliable belief that control would be greater in the future than the past, t(70) = 4.13, p < .001, d = .49.

Study 2 investigated whether this effect emerges even for chance effects in a controlled setting. Participants played a version of Battleship in which they guessed the placement of ships on another person’s board, in two rounds, without feedback. Between the rounds, they rated their control over the past round and then over the upcoming round. Participants believed they would have significantly more control over the outcome of the future round than the past one, t(92) = -2.01, p = .047, d = .27, and the outcome would be more due to their own ability in the future than the past, t(92) = -3.29, p = .001, d = .49.

Study 3 tested whether this difference in perceived control leads people to think they will act differently in the future compared to...
the past. Participants considered a choice between a “should” versus “want” movie (Milman et al. 2009). They were more likely to believe they would choose to watch a “should” movie four months from now than four months ago, \( \chi^2 (1, N = 152) = 5.53, p = .02, \phi = .19 \). Participants also thought the movie decision would be more under their control in the future than the past, \( t(150) = 2.27, p = .02, d = .38 \). Perceived control partially mediated the movie choice, suggesting that participants’ feelings of greater future control led them to believe they would exert greater self-control over a future choice.

Study 4 examined whether people believe they will have greater control over future events than past events even when the consequences of having control are negative (to address the possibility that this asymmetry might be due to general optimism). Participants imagined four situations in which something negative happened (e.g., eating too much at a buffet, drinking too much at a party). They imagined this happening in the past and in the future, and indicated in which of those two time periods the negative behavior would have been more likely to have been under their control. For all four behaviors, participants believed that they would be more likely to “misbehave” for reasons under their control next month than last month, all \( p s < .001 \).

Study 5 similarly looked at whether people perceive greater future (vs. past) control over negative as well as positive outcomes, this time between-subjects. Participants imagined that, either last fall or next fall, they were installing a new DVD player; the installation succeeded or failed. Participants believed that the outcome, either success or failure, would be more due to factors under their control in the future than the past, \( F(1, 199) = 4.53, p = .04, \eta^2 = .02 \). There was no interaction between timeframe and outcome valence (\( p = .57 \)).

Finally, study 6 examined the process underlying this asymmetry. Notably, this asymmetry is actually valid from the perspective of the present: the past cannot be changed, but the future can. We suspect that people substitute their perception that the future is currently open and the past is currently fixed when assessing how controllable the future will be when it happens and how controllable the past was when it happened. To test this idea, we attempted to make the future feel as fixed and unchangeable as the past. Participants read either an excerpt of an essay that claimed that free will exists, or an excerpt that claimed that free will does not exist and that people’s actions are predetermined. Then they completed a version of the DVD player scenario from study 5. Participants in the free-will condition showed the typical pattern of results: the installation seemed more under their control in the future, \( t(201) = 2.99, p = .003, d = .42 \). However, in the no-free-will condition, the future and past seemed equally controllable (\( p = .91 \)). Thus, by shifting participants’ perceptions of the openness of the future, we also shifted their beliefs about how controllable the future was relative to the past.
